Ø

AN EXPERIENCE of more than half a century, which this company and its founders have had with various Steam Engineering Specialties, including the horizontal tubular boiler, the globe valve, the taper screwed joint, and the free end vertical tube radiator, all of which were devised by the late Joseph Nason, should enable its present officers, without egotism, to speak with some authority as to the merit of goods both manufactured and sold by them, and of the care which has been used in the preparation of the present catalogue.

From the very large list of materials made for steam fitters' and plumbers' use, the best only of their kind have been selected for book illustration, and none other will be offered for sale or delivery. The past business policy of the NASON MANUFACTURING COMPANY having been to fully guarantee the quality of all goods sold, customers may rely upon a continuance of the same methods, and all articles which may be found in any way unsatisfactory, or not as represented at the time of sale, may be returned and the cost of transportation charged.

Especial attention is directed to the Nason patented specialties, including particularly the well known "Equator" and "Gulf-Stream" Heaters, which, after several seasons of severe trial under all possible conditions of service, are generally recognized as the best of their class. For this season's delivery, they have been still further improved, if not perfected, by the addition of an entirely new shaking and dumping grate, devised by Mr. Nason especially for them. Of this, full illustration will be found, and these grates will fit heaters of previous manufacture.

It is unpleasant, though necessary, to again have to warn the trade, and steam users in general, that several of the specialties originated and made by this company have been cheaply imitated by competitors lacking sufficient originality to design their own wares. An examination of the latter will invariably show them to be rough in workmanship, notably light in weight, and distinctly unfit for such wear and tear as come from the high pressures incident to modern steam engineering.

This is notably true of Steam Traps. See that the name "Nason" appears upon them, and reject all others. This name belongs to NASON MANUFACTURING COMPANY by right, and if Traps other than those of its make are sold as "Nason" Traps, the sellers render themselves liable to action for selling goods under false representation.

To those contemplating the installation of any kind of apparatus, it may be said that the extended knowledge gained by long experience of the company's staff of engineers makes it often possible for them to be of assistance by advice or suggestion, and such counsel will be always freely and willingly given when wanted.

Tables have been introduced in the latter pages of the book which may frequently be found valuable if used.

Many thanks are extended to friends and patrons of the past, and the good will of those whose acquaintance we may make in the future is earnestly hoped for by

Faithfully yours,

71 Fulton Street,
71 Beekman St.,
April, 1901.

NASON MANUFACTURING COMPANY.

SPECIAL NOTICE.

A large and complete assortment of standard goods is carried in stock at all times. Special articles will be made to order on the shortest possible notice.

All agreements are contingent upon strikes, delays of carriers, and other causes unavoidable, or beyond our control.

Orders for special goods, not suitable for general stock, cannot be countermanded.

Goods returned will be received and credited only under our written consent.

Orders by telegraph and telephone are accepted at sender's risk.

NASON MANUFACTURING COMPANY.

WILL CUSTOMERS KINDLY NOTE THAT:

Business misunderstandings will be avoided and correspondence lessened by reading the following :

1. All lists and discounts are subject to market changes ; but so far as possible customers will be promptly informed of variation in prices.
2. Quotations made will be held open for acceptance for ten days only ; after which, should an advance occur, the agreement to sell at the price named terminates.
3. Terms, cash within thirty days, unless specifically agreed otherwise.
4. Instructions for shipping should be full and the line specified ; when not given, goods will be sent by the most direct route.
5. Boxing, Crating, and Cartage will be charged for at cost.
6. As all goods sent out will be carefully examined, counted, and packed by experienced employees only, responsibility for loss or breakage ceases on delivery to shipping agents, and claims, therefore, must be made on the carrier.
7. Insurance will not be placed on shipments unless requested.
8. Customers will protect their interests by examining goods, when possible, to ascertain if they have been damaged in transit, before signing any receipt for them.
9. Claims for corrections, to receive attention, should be made within ten days after goods are received.
10. Business correspondence, to secure prompt attention, should be addressed, not to its officers or employees, but to the—

NASON MANUFACTURING COMPANY.

NET PRICES OF EXTRA GAUGES OF BOILER TUBES.

To take the place of all previous lists, and subject to change without notice.

For EXTRA wire gauge "Boiler Tubes" away from standard not exceeding four wire gauges, add one cent for each inch in diameter to the net price per foot for each additional number. To calculate price, take discounts from list prices of regular tubes, and add thereto net charge for extra wire gauge, thus :

For 1 Number.	For 2 Numbers.	For 3 Numbers.	For 4 Numbers.
2 inch.....2 cts.	2 inch.....4 cts.	2 inch.....6 cts.	2 inch..... 8 cts.
2¼ "2¼ "	2¼ "4½ "	2¼ "6¾ "	2¼ " 9 "
2½ "2½ "	2½ "5 "	2½ "7½ "	2½ "10 "

Beyond four numbers, price is per pound.

Swaging or swelling 2 inch or 2¼ inch Tubes, 5 cents per end extra.

SAFE ENDS.

Net prices for Safe Ends to 6 inches long, inclusive. Over 6 inches, and not exceeding 12 inches long, the extra length will be charged for in same proportion. Longer than 12 inches from regular Tube List.

Size.....	1	1¼	1½	1¾	2	2¼	2½	2¾	3	3¼	3½	3¾	4	4½	5	6
Each End,	.13	.13	.13	.13	.13	.14	.16	.18	.20	.22	.25	.27	.29	.32	.37	.45

These prices for Safe Ends govern up to No. 10 Bgm. W. G. Beyond that an extra charge will be made at rate of one cent per each inch in diameter for each Extra Gauge per Safe End.

HYDRAULIC TUBES.

¼ inch thick or under.....10 cents per pound.
¼ inch to ⅜ inch thick.....12 " "

Over ⅜ of an inch thick, special prices.

The above prices are for tubes up to 20 feet long—for tubes in excess of that length, ten per cent. will be added to net of invoice.

Extra thickness of tubes will be charged as per list of Extra Gauges.

STANDARD STEAM, GAS AND WATER PIPE.

LIST ADOPTED FEBRUARY 15, 1900.

HEAVY DRIVE WELL PIPE.

WITH THE ALLISON PATENT VANISHING THREAD.

Full lengths range from 18 to 20 feet.

Half " " 9 to 10 "

Third lengths range from 6 to 7 feet.

Fourth " " " 4 ft. 6 in. to 5 feet.

Each length is fitted with one coupling without extra charge.

STANDARD FULL WEIGHT DRIVE PIPE,

Cut in lengths 3 feet to 9 feet long, and threaded specially so that the ends of pipe will butt together when screwed up; with Patent Sockets.

Specially Adapted for Driven Wells. Special Net Prices for Drive Pipe quoted on Application.

SPECIAL TUBING.

We are prepared to furnish special tubing of any practicable internal or external diameter or thickness, with plain surfaces, in iron or steel, or seamless drawn tubes with finished surface inside and out. Such special tubing is made usually to sample or specification.

Price will be quoted on application, based upon current cost at time of inquiry.

STANDARD STEAM, GAS AND WATER PIPE.

1 in. and 1 1/4 in. in 6 ft. lengths; 1 1/2 and 2 in. in 9 ft. lengths; 3 in. and upwards in 12 ft. lengths.

Weights for Lead and Hemp are approximate only.

Full assortment all regular sizes usually in stock.

All standard length Hub and Spigot Water and Gas Pipe sold by the ton; prices based on quantities, or lowest rates current at time of purchase.

Hub and Spigot Specials, Elbows, Tees, Crosses, Reducers, Increases, and reducing specials for all sizes and pressures furnished promptly at lowest price per pound current at time of purchase.

Flanged Cast Iron Pipe and Specials quoted on application.

Inquiries should state sizes, approximate quantities and weights of pipes, or pressures under which they will be used, and if possible, deliveries desired.

Random lengths with threads and couplings will be shipped unless otherwise ordered.
For cut lengths an extra charge will be made above random.
For galvanized or asphalted an extra charge will be made above black.

DOUBLE GALVANIZED SPIRAL RIVETED FLANGED PRESSURE PIPE.

Made of Galvanized Iron, and Re-Galvanized after formation, thereby making all Seams and Laps perfectly solid.

Each length tested to 150 pounds hydraulic pressure, suitable for exhaust steam, exhaust-steam heating, pump suction, pump columns, compressed air, refrigerating pipe, etc.

CAST IRON FITTINGS.

LIST OF STANDARD SIZES.—(ADOPTED JUNE 24, 1897.)

NOTE.—Sizes not mentioned in the following list are to be charged at five (5%) per cent. gross discount higher than those found in the "Standard Sizes."

Elbows, not reducing, $\frac{1}{4}$ to 12-inch inclusive.

45° Elbows, $\frac{3}{8}$ to 12-inch inclusive.

Right and Left Elbows, $\frac{1}{4}$ to 3-inch inclusive.

Tees, not reducing, $\frac{1}{4}$ to 12-inch inclusive.

Crosses, not reducing, $\frac{3}{8}$ to 12-inch inclusive.

Offsets, to offset 4, 6 and 8 inches, $\frac{3}{4}$ to 6 inch inclusive.

Ys, not reducing, $\frac{1}{2}$ to 10-inch inclusive.

Return Bends, Close, $\frac{1}{4}$ to 3-inch inclusive.

Return Bends, Open, $\frac{1}{2}$ to 3-inch inclusive.

Flange Unions, $\frac{1}{2}$ to 12-inch inclusive.

Caps, 2 to 12-inch inclusive.

Locknuts, 2 to 12-inch inclusive.

Plugs, $\frac{1}{4}$ to 12-inch inclusive.

ELBOWS.—REDUCING SIZES.

$\frac{1}{2}$ x $\frac{3}{8}$	$\frac{1}{4}$ x 1	2 x $1\frac{1}{2}$	3 x $2\frac{1}{2}$	4 x 3	6 x 5
$\frac{3}{4}$ x $\frac{1}{2}$	$\frac{1}{4}$ x $\frac{3}{4}$	2 x $1\frac{1}{4}$	3 x 2	4 x $2\frac{1}{2}$	6 x 4
1 x $\frac{3}{4}$	$\frac{1}{4}$ x $\frac{1}{2}$	2 x 1			
1 x $\frac{1}{2}$	$\frac{1}{2}$ x $1\frac{1}{4}$	$2\frac{1}{2}$ x 2	$3\frac{1}{2}$ x 3	$4\frac{1}{2}$ x 4	8 x 6
	$\frac{1}{2}$ x 1	$2\frac{1}{2}$ x $1\frac{1}{2}$	4 x $3\frac{1}{2}$	5 x 4	
	$\frac{1}{2}$ x $\frac{3}{4}$				

REDUCING COUPLINGS.

$2\frac{1}{2}$ x 2	$3\frac{1}{2}$ x $2\frac{1}{2}$	$4\frac{1}{2}$ x 4	6 x 4	10 x 8
$2\frac{3}{4}$ x $1\frac{1}{2}$			6 x 3	
3 x $2\frac{1}{2}$	4 x $3\frac{1}{2}$	5 x 4	7 x 6	12 x 10
3 x 2	4 x 3	5 x 3		
$3\frac{1}{2}$ x 3	4 x $2\frac{1}{2}$	5 x 5	8 x 6	
	4 x 2			

TEES.—REDUCING SIZES.

NOTE.—Tees which reduce on the outlet, thus:

$\frac{2}{1} \frac{1}{4} \frac{2}{1}$
are read, $2x1\frac{1}{4}$.

Tees reducing on run, thus:

$\frac{2}{1} \frac{1}{4} \frac{1}{2}$
are read, $2x1\frac{1}{4}x1\frac{1}{2}$.

Tees with both ends of run the same size, with the outlet larger, thus:

$\frac{1}{2} \frac{2}{1} \frac{1}{2}$
are known as Bull Head, and are read $1x2$.

Reducing on Outlet.	Reducing on Outlet.	Bull Head.	Reducing on Run.

SPECIAL RECESSED FITTINGS FOR WROUGHT IRON DRAINAGE SYSTEMS.

SCREWED.

FOR WROUGHT IRON PIPE.

These fittings have an interior shoulder, and are made with same inside capacity as the inside diameter of the pipe, thus securing an unobstructed surface, allowing all solid matter to pass without choking up the pipes.

CLASS B		Price, 20 cents per pound.
Elbows, $\frac{3}{8}$, $\frac{1}{4}$, $\frac{3}{8}$ x $\frac{1}{4}$, $\frac{1}{2}$ x $\frac{1}{4}$ in.	Drop Ells and Tees, $\frac{1}{2}$ in. & smaller.	R. and L. Elbows, $\frac{1}{2}$ in.
Tees, $\frac{1}{4}$, $\frac{3}{8}$, $\frac{1}{4}$ x $\frac{3}{8}$, $\frac{3}{8}$ x $\frac{1}{4}$ x $\frac{1}{4}$, $\frac{3}{8}$ x $\frac{1}{4}$, $\frac{3}{8}$ x $\frac{1}{4}$ x $\frac{3}{8}$.	Caps, $\frac{1}{4}$ and $\frac{3}{8}$ in.	Waste Nuts, $\frac{3}{4}$ in. and smaller.
Elbows, Side Outlets, $\frac{1}{2}$ in. & smaller.	Lock Nuts, $\frac{1}{4}$, $\frac{3}{8}$ and $\frac{1}{2}$ in.	Chandelier Hooks, all sizes.
Tees, Side Outlets, $\frac{1}{2}$ in. and smaller.	Reducing Couplings, $\frac{3}{8}$ x $\frac{1}{4}$ to $\frac{3}{4}$ x $\frac{3}{8}$, inclusive.	Return Bends, $\frac{3}{8}$ and $\frac{1}{2}$ in.
Street Ells, $\frac{1}{4}$ and $\frac{3}{8}$ in.	Extension Pieces, $\frac{3}{8}$ and $\frac{1}{2}$ in.	Return Bends, R. and L., $\frac{3}{4}$, 1 in.
Crosses, $\frac{1}{4}$, $\frac{3}{8}$, $\frac{1}{2}$ in.	R. and L. Couplings, $\frac{1}{4}$ and $\frac{3}{8}$ in.	Wall Plates, all sizes.
Reducing Crosses, 1 in. and smaller.	R. Hand Couplings, $\frac{1}{4}$ and $\frac{3}{8}$ in.	45° Ells, $\frac{1}{2}$ in. and smaller.
		Y's, $\frac{1}{2}$, $\frac{3}{4}$ in.

CLASS C		Price, 16 cents per pound.
Elbows, $\frac{1}{2}$, and $\frac{1}{2}$ x $\frac{3}{4}$.	Drop Tees, $\frac{3}{4}$ in. and larger.	Extension Pieces, $\frac{3}{4}$ in. and larger.
Elbows, R. and L., $\frac{3}{4}$, 1 in.	Caps, $\frac{1}{2}$, $\frac{3}{4}$ and 1 in.	Waste Nuts, 1 in. and larger.
Tees, $\frac{1}{2}$ and $\frac{1}{2}$ in., reducing.	Lock Nuts, $\frac{3}{4}$, 1, $1\frac{1}{4}$ in.	Return Bends, $\frac{3}{4}$, 1 in.
Elbows, Side Outlets, $\frac{3}{4}$ in. & larger.	Reducing Couplings, $\frac{3}{4}$ x $\frac{1}{2}$ to 1 in., inclusive.	45° Ells, $\frac{3}{4}$ to 2 in., inclusive.
Tees, Side Outlets, $\frac{3}{4}$ in. and larger.	R. and L. Couplings, $\frac{1}{2}$, $\frac{3}{4}$ in.	Y's, 1 in. and larger.
Street Ells, $\frac{1}{2}$, $\frac{3}{4}$, $\frac{1}{2}$ x $\frac{1}{4}$ in.	R. H. Couplings, $\frac{1}{2}$, $\frac{3}{4}$ in.	Return Bends, R. and L., $1\frac{1}{4}$ in. and larger.
Crosses, 1 and $\frac{3}{4}$ in., straight.		
Drop Ells, $\frac{3}{4}$ in. and larger.		

CLASS D		Price, 13 cents per pound.
Elbows and Tees, $\frac{3}{4}$ and 1 in.	Lock Nuts, $1\frac{1}{2}$ in. and larger.	Return Bends, $1\frac{1}{4}$ in. and larger.
Crosses, $1\frac{1}{4}$ in. and larger.	Reducing Couplings, $1\frac{1}{4}$ in. & larger.	R. and L. Couplings, 1 in. and larger.
Street Ells, 1 in. and larger.	R. H. Couplings, 1 and $1\frac{1}{4}$ in.	45° Ells, $2\frac{1}{2}$ in. and larger.
Caps, $1\frac{1}{4}$ in. and larger.	Such Fittings as have smaller outlets than $\frac{3}{4}$ inch will be classed "C."	
R. and L. Elbows, $1\frac{1}{4}$ and larger.		

CLASS E		Price, 11 cents per pound.
Elbows and Tees, $1\frac{1}{4}$ in. and larger.	Right Hand Couplings, $1\frac{1}{2}$, 2 in.	Such Fittings in this class that have outlets smaller than 1 inch to be classed "D."

The run of Tees (Bullheads) gives the size for the purpose of classification, and the outlet being larger does not change it. Return Bends, reduced, Return Bends, spread, Elbows tapped on pitch, 15 per cent. added.

MALLEABLE IRON RAILING FITTINGS.

FOR FENCES, ENCLOSING ENGINES AND MACHINERY, EXHIBITION SPACES, ETC.

In ordering these Railing Fittings be careful to state whether *right hand* or *left hand* threads are wanted. Where Fittings are required having *right* and *left hand* outlets, please fully describe which are wanted RIGHT HAND and which LEFT HAND. A careful observance of the above will save much trouble and secure the accurate filling of your orders.

BLAKE'S PATENT MALLEABLE IRON PIPE HANGER,

WILLIAMS' PATENT ADJUSTABLE BEAM CLAMP.

THE BLAKE HANGER has no equal for simplicity, strength, and ease of adjustment. It can be attached to pipe when in position; it has no troublesome screws to adjust; it provides for expansion; it is adjustable to any desired pitch-lines of mains. It is the most economical and popular hanger in the market, and is endorsed and extensively used by the leading houses supplying the steam heating and plumbing trades throughout the United States.

THE B. & W. BEAM CLAMP. Figure 9 shows the Blake Hanger attached to a new and important improvement in Adjustable Beam Clamps. This clamp is made in three sizes,—No. 1, suitable for iron beams two to four inches; No. 2, for iron beams four to six inches; and No. 3, for iron beams six to eight inches. They are readily adjusted, and provide for an expansion movement in hanger attachment.

The combination of this clamp with the Blake Hanger is the most complete, satisfactory, and practical device for the purpose ever placed on the market.

UNIVERSAL PIPE HANGER.

No. 1.

PATENTED JUNE 24TH, 1890.

No. 2.

The "Universal" Hanger allows for expansion to the right and left, as well as forward and backward.

It is simple and easy of adjustment. Can be attached to pipe when in position.

The lag screw may be extended to any length by means of iron pipe and coupling.

Style D..	16	18	20	22	24	26	28	32	34	38	42

Style A, fitted with lag screw to thread into wooden beams. If desired, the screw can be turned at right angles by removing the bolt.

Style C, fitted with I Beam Plate Hanger.

Style D. This style is used most. The end can be bent to any desired angle.

Four inches of our extension bar is allowed to each hanger ordered, but the entire amount for a given order is included in uncut lengths, to more readily conform to different requirements

STEEL EXTENSION BAR.—10 FEET LENGTHS.

12 gauge x $\frac{3}{8}$	8c. per foot.	for 1 and 2 inch pipe.

9 " x $1\frac{3}{8}$		
8 " x $1\frac{1}{2}$		

Un.versal Steel Pipe Hook.

Made of first quality soft steel, and requiring but one screw to fasten. As the barbs are driven they draw the wood between them together, thus preventing splitting when the nail or screw is inserted. The end is long enough to turn over on the top of the pipe, thus holding it firmly in the hook. It makes a strong and neat job.

JENKINS' SWING CHECK.

Simplicity.—It can be repaired by simply removing cap and renewing the disc.

Durability.—As it is not metal against metal, there is no chance for the seat to wear—the only wear being on the Jenkins Disc.

Economy.—It has been demonstrated that the average life of a Jenkins Disc in use in Check Valves is from eight to ten years; consequently, the saving in disconnecting and regrinding the valves alone makes it the most economical.

LUDLOW BRONZE VALVES, DOUBLE GATE.

Tested at 300 lbs. pressure per square inch, water pressure. Test guaranteed.

SCREWED ENDS

with Screwed Cover and Rising Stem. Style of sizes, $\frac{3}{8}$, $\frac{1}{2}$, $\frac{3}{4}$ and 1 inch.

SCREWED ENDS

with Screwed Cover and Screwed Stuffing Box. Style of sizes, $1\frac{1}{4}$, $1\frac{1}{2}$ and 2 inches.

SCREWED ENDS

with Bolted Cover and Screwed Stuffing Box. Style of sizes, $2\frac{1}{2}$ to 6 inches, inclusive.

SCREWED ENDS

with Bolted Cover, Bolted Stuffing Box and Follower. Style of sizes, 7 inches and above.

FLANGED ENDS

with Bolted Cover, Bolted Stuffing Box and Follower. Style of sizes, 7 inches and above.

SLIDING STEM AND LOCK LEVER VALVE.

With this arrangement the Gates can be opened or closed by a single movement, or held in any desired position by the Locking Lever. In small sizes a wheel takes the place of Locking Lever.

BRONZE VALVES—Double Gate.

THE "N" RADIATOR VALVE.

WITH UNION.

The need for a Radiator Valve which, while handsome in appearance, and of good material and workmanship, is low in price and amply good for working pressures up to ten pounds, has induced us to go into the manufacture and output of such a valve, cuts of which are submitted.

They are made both with and without unions and all are fitted with

JENKINS' DISCS.

The list for these valves is the same as the regular price list.

WITHOUT UNION.

DISCOUNTS WILL BE GIVEN ON REQUEST.

AUTOMATIC RADIATOR AIR VALVES.

THE DAVIS No. 7 (FLOAT)
AIR VALVE.

Closes both by floatation and expansion.

The constant adjusting hitherto required by valves of this description is a constant annoyance. This is caused by the gradual shrinkage or compression of the expanding composition.

By our construction this fault is entirely overcome. We recommend this valve for use where it is impossible or undesirable to run drip pipes to basement.

All valves nickel plated.

Each.....	\$ 1.25
Per dozen.....	15.00

AUTOMATIC RADIATOR AIR VALVES.

"EUREKA"

AUTOMATIC AIR VALVES

Have a hollow, closed float, light and buoyant; rises from the least water and closes valve. Valve stem is riveted to top of float and made of gun metal, so will not corrode. Have a hard rubber expansion cylinder, that elongates or expands $\frac{3}{4}$ in. from the top. Owing to the deflector attached to bottom of cylinder no in-rushing air or steam can reach float to raise it by pressure. They are all tested at 100 pounds pressure, and adjusted to close against steam as soon as the heat reaches the valve, and against the leakage of water soon as it reaches the float, adapting them for either steam or water.

Cap screws on, and can be locked with the plyers, so no meddling with the adjustment. All joints are screw threaded. No soldered joints. Adjusting screw passes through a stuffing box and is packed so no leakage around thread. They are adjusted at factory. Anyone can apply them. Made side inlet, for radiators. Bottom inlet, for coils, indirect, steam traps, etc. Price, each.....\$1.00

With Heat Controller attachment, useful in mild weather when but little heat is required, as a portion of the radiator can be made inoperative, making it unnecessary to open and close supply valve.

No. 2

Price.....\$1.15
15c. extra each net for Heat Controller attachment.

"VAN AUKEN" PATTERNS.

A thoroughly tried and fully guaranteed valve of the highest grade.

Perfected Duplex No. 1.
Price.\$1.15 each.

Has a tube connection to conduct foul air from radiator into basement, or elsewhere, so that it will not be discharged into occupied room. Designed for fine residence work.

No. 4

Price.\$1.55 each.

THE "PERFECTION."

Per dozen..... \$12.00

"AMERICAN" SPECIAL NON-CORROSIVE COMPOSITION STEM.

"American."

Which, owing to superior construction, can be brought with great force against the valve-seat without turning or injury to either. This feature makes the "American" practically indestructible. The Special Composition Stem will not corrode nor adhere to the valve seat, as would be the case if it were capped with metal faces.

"AMERICAN, JR."

After adjusting the little set screw it can be used as a positive valve without change, and cannot be tampered with. The Expansible Stem cannot be injured by screwing down the operating piece too tight.

Price, each.....\$1.00

"American Jr."

MONASH HOT-WATER AIR-VALVE.

The Monash Positive and Automatic Hot-Water Air-Valve is recommended as the most practical and successful automatic valve yet devised for use with hot water.

List price, each..... \$3.00

JENKINS IMPROVED AUTOMATIC AIR VALVES.

SUITABLE FOR HIGH OR LOW PRESSURE.

DESCRIPTION.—A, inlet; B, screw for setting; C, an expansible plug; D, outlet, tapped to connect drip-pipe or drip-cup.

These Joints are made of soft seamless drawn corrugated copper tubes, which close with the expansion and open with the contraction of the line of pipe in which they are placed. We guarantee satisfaction when placed in accordance with our directions.

DAVIS NOISELESS BACK-PRESSURE VALVE.

The Davis valve is constructed on an entirely new and unique principle. Instead of a flat valve to hammer the seat at each stroke of the engine, it has a sliding valve which renders it *perfectly noiseless in operation*. This valve consists of two seats, but of different areas, and instead of the resistance of the whole area of the pipe to weight back *as on all other valves*, the resistance is only the difference in the area of the two seats, one partly balancing the other. By this construction only one-quarter the usual amount of weight is required even for high pressure.

Each valve full area of corresponding size of pipe.

In ordering valves for condensing engines it must be so stated, as all valves are made for non-condensing engines unless otherwise ordered.

Valves are not fitted tight unless so ordered.

* Valves from 3 to 7 in. inclusive made either flanged or screwed end. Larger sizes flanged end only.

THE KIELEY NOISELESS BACK-PRESSURE VALVE.

The Kieley Valve is simple in construction, is guaranteed absolutely noiseless and steam tight. It is extremely sensitive, and can be regulated to carry any back pressure that may be required. The lever can be placed in any position desired by simply turning the top.

The valve is made for both vertical and horizontal mains.

NASON'S QUICK OPENING ELEVATOR VALVE WITH BALANCED DISCS.

They are offered to the trade as the most reliable valve made for the automatic and positive control of the speed of all pumps and engines which are used for tank service in connection with elevators, or for pumping water into reservoirs for general use.

A small difference in the diameters of the two discs permits the passage of the lower through the upper opening. Compensation for the difference in areas is provided by the weighted lever.

Being connected in the line of steam supply to the pump to be regulated, they are operated by a float placed either in the upper or lower tank of the elevator, and as a movement in the valve spindle of from $\frac{1}{2}$ in. to 2 in. (depending upon its size) is sufficient to entirely open or close it, their extreme sensitiveness is apparent.

This valve is made as shown in the above cut, either with yoke, lever, and weight, or without these additions, the spindle being in the latter case left plain on the upper end, as with our regular Balanced Disc Governor Valve.

Sizes.....	1 in.	1 $\frac{1}{4}$ in.	1 $\frac{1}{2}$ in.	2 in.	2 $\frac{1}{2}$ in.	3 in.	3 $\frac{1}{2}$ in.	4 in.

NASON'S BALANCED GOVERNOR VALVE. FOR STEAM ONLY.

Balanced Governor
Valve.

In this valve the port openings are of exactly the same size. The openings are each fitted with cylindrical plugs, which are ground with extreme care into the ports and work with a minimum of friction.

As the areas are identical no compensating weight is necessary, and the valve is balanced at all points of its stroke.

Owing to the method of constructing the bearings and the liability to wear if a lubricant is not used, or in the presence of grit or sediment, they are recommended for steam use only.

FOSTER PRESSURE REGULATORS.

NEW "CLASS W."

CLASS "W."

IMPORTANT FEATURES.

1. A compensating spring movement exerting a uniform power on the diaphragm, without regard to the opening of the valve.
2. A compensating balanced valve insuring steam tight seats, regardless of pressure or temperature.
3. Full steam-way through the valve.
4. Great simplicity of construction and operation.
5. No friction of parts.
6. No ports to become clogged.
7. No dash-pot.
8. Noiseless—no "chattering."
9. Can be taken apart for regrinding or repairs, without removal from pipe.
10. Used either as an angle valve, or as a straightway valve.
11. Diaphragm and springs can be removed or renewed without shutting off steam, and in event of these or their connecting parts breaking, the valve will continue to deliver steam while repairs are being made.

12. It is a perfect Pump Governor, capable of controlling a pump operating pressures from 5 to 5,000 lbs.

13. The whole operation, either as a Pressure Regulator or a Pump Governor, is absolutely automatic, requiring no attention after once being adjusted as to pressures.

Size.....	1/8	3/4	1	1 1/4	1 1/2	2	2 1/2	3	3 1/2	4	5	6	7	8	10	12	14	16	18

CLASS "Q."

NEW "CLASS Q."

FOR STEAM HEATING.

This new Reducing Valve is specially designed for Steam Heating, or for other service where the delivery pressure does not exceed 15 lbs. on the square inch.

It is not intended to take the place of the Foster Standard "Class W," but to meet the demand for a lower priced valve for some services where it will answer its purpose as well as a more expensively constructed one.

The diaphragm is composed of sheet rubber, which any engineer can renew, and is protected from the heat of the steam by water of condensation. It is also protected by steel backing plates which prevent undue strain or expansion of the rubber.

THE "FORD" PUMP REGULATOR.

FOR ELEVATOR, HOUSE AND FIRE PUMPS.

To connect and operate, place the Regulator in an upright position between the steam chest and throttle valve, then connect the steam pipe to the side inlet. The oil cup should be placed in such a position as to allow the oil to pass through the Regulator. For connecting the water part with closed tank (as with elevator pressure systems or fire pumps), tap the pressure tank for 3/8 pipe, and connect the side of operating cylinder (marked inlet). Place a union and globe valve near the Regulator. A drip pipe should be connected with the bottom of the cylinder.

To remove the valve cap, strike the lugs lightly with a hammer.

In starting your pumps, do it with throttle valve in steam pipe, then open the globe valve in pressure pipe from tank to Regulator, and screw up the nuts on side rods under the spring rest until the required pressure is obtained.

When used for open tanks connect a float valve to the end of discharge pipe in the tank on the roof; then from the operating cylinder connect a 3/8 pipe to the pump discharge pipe with a valve and union.

Ford
Water Pressure
Regulator.

THE
"GRIFFIN" WATER
PRESSURE REGULATOR.

In the "Griffin" Water Pressure Reducing Valve, we present a device which we can recommend for its simplicity of construction, durability and absolute safety.

By its use heavy water pressures are automatically reduced and maintained at any point at which the Regulator may be set ; all its parts are frictionless, and there are no packed joints to leak or stick.

It is not an untried device, having been in the field for several years, and during which time a large number have been placed under the most exacting conditions with perfect results in every instance. By a simple device the full initial pressure can be instantly turned on for fire or other purposes, and can be operated from a long distance, balancing the water on opposite sides of the diaphragm, relieving it from all strain, unlike any other. A bonnet and wheel furnished with 2-inch sizes and above, forms a shut-off globe valve.

This Regulator does not chatter under heavy pressure and full flow ; its use prevents the annoying "water hammer" in house systems, and in case of mains being turned off, or bursting, the valve closes automatically and prevents the collapse of Boilers.

SPECIAL STEAM WHISTLES.

Long Bell Whistle.

Organ Pipe Whistle.

ORGAN PIPE WHISTLE.

The Organ Pipe Whistle, owing to its length and form of bell, has a soft and musical far-reaching sound, and is therefore, in many cases, preferable to the shrill sound of the plain whistle, especially when worked under high pressure. It has been largely adopted by steam launches, etc.

PRICES.

Diameter of Bell, inches	1 1/4	1 3/4	2 1/4
Size of Steam Pipe, "	1 1/2	1 1/2	1
Price, each	\$8.00	10.00	15.00

LONG BELL WHISTLE.

The Long Bell Whistle, owing to its length, has a soft and far-reaching sound, and is therefore preferable to the shrill sound of the plain whistle when operated under high pressure.

They are made in the following sizes :

Size of Steam Pipe, "	1	1 1/4	1 1/2	2	2 1/2
Length of Bell	Ranging from 16 to 36 inches.				

Prices upon application.

In ordering, state Length and Diameter of Bell.

STEAM SYRENS.

PATENT APPLIED FOR.

Fig. 18.

Fig. 17.

Fig. 19.

These Syrens are specially constructed for use on board steamships, and will be found to possess advantages greatly superior to any other steam sounding or signaling apparatus. The following among other advantages will be readily understood and appreciated.

They give the most intense, far-reaching, and distinctive sound yet obtained.

They cannot be over-blown, even with the highest pressure, as is the case with Bell or Organ Pipe Steam Whistles.

With the Fixed Cowl the sound is projected in a horizontal direction; the Syren may be fitted to look forward, so that the most concentrated sound will be projected in the direction of the steamer's course.

With the Movable Cowl the Syren becomes in acoustics what the electrical search-light is in optics, as the sound may be projected horizontally in any required direction.

THE VOLUNTEER UP-DROP SIGHT-FEED LUBRICATOR.

FOR STATIONARY ENGINES AND PUMPS OF ALL KINDS.

DIRECTIONS FOR APPLICATION.

1.—Connect the Lubricator to steam pipe by discharge shank G, which is chased for a $\frac{3}{8}$ in. and $\frac{1}{2}$ in. pipe, according to size, and also top of condenser to same pipe by $\frac{1}{4}$ in. pipe, placing a common $\frac{1}{4}$ in. globe valve at the bend, as illustrated.

2.—The connection between shank G and main steam pipe must be above the throttle, so that pressure will remain on the cup when throttle is closed.

DIRECTIONS FOR USE.

Fill the cup with clean strained oil through filling plug A, then open valves B and D; wait till sight-feed glass has filled with water of condensation, then start and regulate the feed by valve C.

To Stop.—Close valve C.

When the cup is empty close valves C and D, and draw off water by waste-cock W; then fill and start as before, always opening valve D first.

NOTES.

1.—In case the sight-feed glass breaks, close valves B and C and remove the broken glass by unscrewing bonnet of water valve D; at all other times valves B and F must be kept open.

2.—Keep valve D always open, except when draining the cup, as per directions.

- K. Connection to Steam Pipe or Steam Chest. (Single Connection.)
- Q. Drain Valve for Sight-Feed Glass.
- I. Valve in Support Arm. (Single Connection.)
- F. Steam Connection. (Double Connection.)
- M. Connection to Steam pipe. (Double Connection.)

Double Connection.

The Single Connection Style "C" Lubricator should be attached to the steam pipe below the throttle or into the steam chest direct.

The Double Connection Style "C" Lubricator should take the steam from the boiler direct, or from steam pipe above throttle, and discharge the oil either into steam pipe below the throttle, or into the steam chest or cylinder. Its construction is such that the oil cannot be siphoned out, and a regular and steady feed is obtained.

Size.....	$\frac{1}{4}$ Pint.	$\frac{1}{2}$ Pint.	$\frac{3}{4}$ Pint.	Pint.	Quart.
Brass Finish, each.....	\$15.00	17.00	20.00	28.00	42.00
Nickel Plated, each.....	18.00	20.00	23.00	32.00	47.00

There are about 6,000 drops of cylinder oil to the pint. Some oil companies claim as many as 6,600 drops per pint. Each Lubricator is tested under 300 lbs. pressure.

DETROIT SIGHT-FEED LUBRICATORS

FOR GAS AND GASOLINE ENGINES, AIR COMPRESSORS AND AMMONIA CYLINDERS.

Gas Engine and Air Compressor Lubricator.

- A. Oil Reservoir.
- C. Filler Plug.
- D. Valve to control admission of Air.
- E. Feed Valve, with Stop Feed feature.
- H. Sight-Feed Glass.
- K. Connection to Cylinder.
- L. Plug to insert glass.

Size of Glass..... $\frac{5}{8} \times 2\frac{1}{8}$

The Gas Engine and Air Compressor Lubricator is made of the best brass and is connected to the cylinder direct.

For large gas engines and powerful air compressors a specially strong lubricator of this pattern is made.

The "Detroit" Ammonia Cylinder Lubricator is composed of special material which is not affected by the action of Ammonia. It is attached into Ammonia Cylinder Head.

Regulate pressure by Valve D and flow of oil by Valve E. Valve E may be shut off at any time and opened again without disturbing the feed.

Ammonia Cylinder Lubricator.

Size.....	$\frac{1}{4}$ Pint.	$\frac{1}{2}$ Pint.	$\frac{3}{4}$ Pint.	Pint.	Quart.

IMPROVED "HANDY" DROP-FEED LUBRICATORS.

Nos. 1 and 2.
Without Oil Gauge.

FOR STATIONARY
AND
PORTABLE ENGINES
OF ALL KINDS,
STEAM PUMPS, ETC.

- A—Filling Plug.
- B—Bottom Steam Valve.
- C—Regulating Valve.
- D—Top Steam Valve.
- E—Waste Cock.
- F—Gauge Glass.

Nos. 3 to 7.
With Oil Gauge.

THE SUPPLY OF OIL is propelled through the sight-feed glass by an improved process of steam condensation, and may be regulated to feed fast or slow according to the demands of the engine. The above cuts represent it as applied to the steam pipe, which is the best and most convenient position. Sizes above and including No. 3 are provided with a gauge glass, to show at all times the quantity of oil remaining in the Cup.

DIRECTIONS FOR APPLICATION. Attach the cup to main steam pipe, as close as possible, by a short nipple and elbow at the bottom, taking care the angle does not sag. Connect the valve accompanying the lubricator to the little elbow on top of cup, and to the main steam pipe by 1/8 in. pipe, in the most convenient position.

DIRECTIONS FOR USE.—Fill the cup through filling plug A with clean strained oil. To START:—Open bottom steam valve B, one-half turn, and top steam valve D wide, then after waiting a few minutes, open valve C, when the drop will fall down in sight-feed glass. Regulate the feed by valve C, according to size of engine, but not to exceed 50 drops per minute. To STOP:—Close valves C and B. When the cup is empty, close all valves and draw off condensed water and impurities by waste cock E; then fill and start as before.

Size.....	No.	1	2	3	4	5	6	7

PLAIN TAPER SCREW ENGINE OILERS.

WITH SIGHT FEED.—SKELETON FRAME.

This style of Cup is made with openings in Ball Shanks, protected by glass, to show the oil drop as it leaves the Cup. This enables the engineer to see the progress of feeding, and regulate flow according to the required demand. They are further provided with an opening in the top, having a movable cover, through which they may be filled, and which also acts when shut (which it should always be, except in the act of filling) as a vent sufficient to keep a proper degree of circulation of air in the Cup to make the pressure uniform and facilitate the flow of oil.

SERIES 160.

NICKEL-PLATED OILERS.

SKELETON FRAME. FOR SHAFTING AND ENGINES.

In these Cups the supply of oil is regulated by means of a graduating slotted heavy brass wire, and is capable of being increased or diminished with the utmost precision by adjusting this wire, which extends upward through the centre of the cup, and is easily reached by removing the knob. A slot in the knob enables the latter to be used as a wrench, to adjust the regulating screw to the desired point. This most convenient device has been patented, and cannot be applied to any oil cups except those we manufacture, without liability for infringement of patent.

SERIES 120.

NICKEL-PLATED STOP
AND SIGHT FEED OILERS.

SKELETON FRAME.

In these Cups the feed is controlled by the Regulating Screw in the top Cross-bar, and may be set to any desired rate by means of the small lock nut on same. The supply of oil can be shut off, or turned on instantly, without disturbing the rate of feed by the seating and unseating of the Regulating Screw in the socket on top of the Cup. They are also provided with Ball Shank Sight Feed Openings protected by glass, through which the flow of oil is visible at all times, and a filling hole in the top of the Cup fitted with a movable cover which acts at the same time as a ventilator to keep up a proper circulation of air in the Oil Chamber.

WATER COLUMNS.

THE "RELIANCE" HIGH AND LOW WATER ALARMS—IRON JAPANNED.

Column
Full Trimmed.

Showing High and
Low with two
floats.

Showing low alarm
one float only.

- No. 1. Not guaranteed to work above 80 lbs. pressure. Variation between alarms 6". Size of water gauge and gauge cocks $\frac{1}{2}$ ". Size of steam and of water connections 1". Untrimmed \$28.00.
WITH WATER GAUGE AND GAUGE COCKS \$35.00.
- No. 1½. For any ordinary pressure. Variation between alarms 6". Size of water gauge and gauge cocks $\frac{1}{2}$ ". Steam and water connections $1\frac{1}{4}$ ". Untrimmed \$28.00.
WITH WATER GAUGE AND GAUGE COCKS \$35.00.
- No. 5. For any ordinary pressure. Variation between alarms 8". Size of water gauge and gauge cocks $\frac{3}{4}$ ". Steam and water connections $1\frac{1}{4}$ ". Untrimmed \$30.00.
WITH WATER GAUGE AND GAUGE COCKS \$40.00.
- No. 7. For Water Tube Boilers. Variation between alarms 12". Size of water gauge and gauge cocks $\frac{3}{4}$ ". Size of steam and water connections $1\frac{1}{2}$ ". Untrimmed \$40.00.
WITH WATER GAUGE AND GAUGE COCKS \$50.00.
- No. 9. For Vertical Boilers. Variation between alarms 18". Size of water gauge and gauge cocks $\frac{3}{4}$ ". Size of steam and water connections $1\frac{1}{2}$ ". Untrimmed \$40.00.
WITH WATER GAUGE AND GAUGE COCKS \$50.00.
- No. 11. Variation between alarms 24". Size of water gauge and gauge cocks $\frac{3}{4}$ ". Size of steam and water connections $1\frac{1}{2}$ ". Untrimmed \$42.50.
WITH WATER GAUGE (DOUBLE) AND 3 GAUGE COCKS \$57.50.
- No. 13. Variation between alarms 30". Size of water gauge and gauge cocks $\frac{3}{4}$ ". Size of steam and water connections $1\frac{1}{2}$ ". Untrimmed \$45.00.
WITH WATER GAUGE (DOUBLE) AND 4 GAUGE COCKS \$65.00.
- No. 15. Variation between alarms 36". Size of water gauge and gauge cocks $\frac{3}{4}$ ". Size of steam and water connections $1\frac{1}{2}$ ". Untrimmed \$50.00.
WITH 48" (DOUBLE) WATER GAUGE AND 4 GAUGE COCKS \$70.00.

These columns are made regularly up to 60" variation between alarms, and can be made of any variation for any purpose where steam or compressed air is used.

LOW WATER ALARMS.

- No. 2. Not guaranteed to work perfectly above 100 lbs. pressure. Gauge cocks 3" apart. Water gauge centers 14". Water gauge and gauge cocks $\frac{1}{2}$ ". Steam and water connections 1". Untrimmed \$25.00.
WITH WATER GAUGE AND GAUGE COCKS \$32.00.
- No. 6. For any ordinary pressure. Water gauge and gauge cocks $\frac{3}{4}$ ". Water gauge centers 16". Gauge cocks 4" apart. Steam and water connections $1\frac{1}{4}$ ". Untrimmed \$28.00.
WITH WATER GAUGE AND GAUGE COCKS \$37.00.

VARIATION.—Do not make a mistake by selecting a column of too little variation.

They are as sure to whistle when the water reaches the alarm line as they are to remain quiet while it is kept between these points, and too narrow a limit may prove annoying. The No. 5 is the most popular size with users of horizontal boilers, but also depends upon the fluctuations of the water. Do not select too small a column. The attendant will try to carry the water steadily midway between the alarms anyway, no matter how far they are apart.

THE "METROPOLITAN" PRESSURE RECORDING GAUGE.

The Metropolitan Recording Gauges are made for steam, water, gas, air, ammonia, and hydraulic pressures, also, for Vacuum. For use with ammonia and hydraulic pressures they are provided with steel tube springs.

The "Metropolitan" Recording Gauge, under a glass cover, with wall-bracket, for steam, gas, or water pressure, not exceeding 300 lbs. per square inch,.....	\$100.00
The "Metropolitan" Recording Gauge, mounted as above, for ammonia pressure,.....	150.00
The same, for hydraulic pressure up to 20,000 lbs. per square inch,.....	150.00
(The above prices include 100 charts, a file for same, and a bottle of ink.)	
Additional Charts, per hundred,.....	1.50
File for same,	3.00
Recording Ink, per bottle,.....	.25

Gauges and Charts for the following pressures are kept in stock :

For steam, gas and air.....25, 50, 75, 150, 200 lbs. per square inch.
For water.....100, 200, 300 feet of water column.

“COLUMBIA” PRESSURE RECORDING GAUGE.

Fig. 92.

It consists of a Bourdon Tube Spring of suitable form in connection with a novel adjustable lever mechanism and a pointer, which carries the marking pen. It is provided with a clock movement, to which is attached a metal disc with the chart, making one revolution every 24 hours.

The circular lines on the chart indicate the pressure, while the radial arcs correspond to the hours of the day.

These Gauges are adapted for recording the pressure of steam, water, gas or air, and may be placed near the boiler, or at any distance therefrom—for instance, in the office—always giving a true record of the fluctuations of pressure taking place in boiler, water and gas pipes, etc. They are made for all pressures.

Gauges and charts for the following pressures are kept in stock :

For steam, gas and air,..... 25, 50, 75, 150, 200 lbs. per square inch.
For water,..... 100, 200, 300 feet of water column.

“Columbia” Recording Gauge, in highly japanned iron case, with hinged brass cover and lock, including 100 charts,.....	\$50.00
The same, with Electric Alarm Attachment,.....	60.00
Additional Charts, per hundred,.....	.75
Recording Ink, per bottle,.....	.25

SECTIONAL BLOCKS.

$\frac{1}{2}$ to $3\frac{1}{2}$ in. thick.

for Boilers, Drums, and Large
Surfaces.

Special Prices.

MAGNESIA FIBROUS COM- POSITION.

DRY AND PLASTIC.

Per Barrel or Bag.....\$5.00

Made in 3-ft. Sections. Canvas Jacketed, with Bands.

This covering combines the fibrous strength of Asbestos with the lightness of Magnesia,
and insulating qualities of both, in moulded form. Approved by steam users, and recom-
mended as a cheap and serviceable non-conductor of heat.

STUD BOLTS.

ROUGH IRON, WITH CHAMFERED AND TRIMMED HEXAGON NUTS.

Price per 100.

Thickness of material to be fastened should always be stated when ordering bolts.

These bolts can be furnished with either Square, Hexagon or Countersunk Heads.

Bolts and Expansions made in Brass when required.

The action of these bolts is here illustrated. The wedge head of the bolt and the expansion over it is put into the hole; then the work to be fastened is put on, and then a common nut serves to draw up the bolt, which will cause it to expand and firmly fix the whole together, also shown.

HOT WATER EXPANSION TANKS.

This cut represents an Expansion Tank for Hot Water Heating which is made of the best material and heavily galvanized. All are thoroughly tested under pressure before being shipped, and are supplied with all necessary openings for pipe connections and water gauge.

These tanks are tapped top and bottom 1 inch, and on the side $\frac{1}{2}$ inch for water gauge, and are also tapped on the side for 1 inch water supply.

IDEAL AUTOMATIC EXPANSION TANKS.

The Expansion Tank above illustrated, aside from being ornamental, is absolutely automatic in its operation, *insuring always that the system will be full of water*, and in this respect will prove a great convenience to the house-owner. The Tank is made of hardwood, dovetailed corners, having a tight cover, and lined with sheet copper. It can be supplied in any finish of

wood, to harmonize with the finish of room in which it is installed. It does not require altitude gauge, nor guage glass and fittings. The price asked makes it easily available without increasing expense of the job. Inside measurements of Tank are: 20 inches long, 9 inches wide, 10 inches deep; and of ample capacity for use on any job of hot-water work to which there is attached 2000 feet of radiation or less. Larger sizes made on special order.

PRICE LIST FOR TANKS. (Including expansion and over flow couplings, with iron pipe threads.)

MISCELLANEOUS.

THE "GOOD" BATH AND BASIN STOPPERS.

Basin Stopper.

The most convenient stopper made. There are only two sizes. These fit any basin, bath, laundry tub or wash tray; never allow a leak, even if outlet is not perfectly round; overcome all objections to the common metal and plug stoppers.

Bath Stopper.

Basin Size, per dozen.....\$4.20 Bath Size, per dozen.....\$6.00

1¾ inch Brass N. P. Bath Tub Overflow and Waste con- nection with Ell Top, with Tee and Clean-Out Plug..	3.60

LYONS-FULLER BASIN COCK.

This cock can be used either right or left by removing the bibb and plug and replacing them on the proper side, adjusting them by means of a lock-nut, which is used also for preventing the bibb from leaking.

In this cock the construction of the valve is such as to insure entire freedom from "hammering" or "rattling."

An eccentric stem, in two parts, insures a positive seating of the valve at all times and a consequent freedom from leakage.

The valve being encased, is not exposed to water flowing through it, which insures the greatest possible durability.

Nickel Plated, per doz. \$44.00

LEAD PIPE.

SHEET LEAD, weight per square foot, pounds, $2\frac{1}{2}$, 3, $3\frac{1}{2}$, 4, $4\frac{1}{2}$, 5, 6, 8, 9, 10 and upwards.

When Branches are 2 feet long, add price of 1 foot of pipe, and when 3 feet long, price of 2 feet to this list.

REDUCERS AND INCREASERS.—Measured at largest opening, and charged for on the basis of 4 feet of pipe, corresponding with internal diameter of opening.

SLANTS, 12, 18, 24 and 36 inches long, (measured on long side), price of plain pipe with 50 per cent. added.

“HANDY” FORCE AND SUCTION PUMPS.

Will force out obstructions in any Closet, Bowl, Sink, Tub or Urinal.

Length of Handle, 4 feet. Weight less than 2 lbs.

List, each \$3.75

DIRECTIONS FOR USING.

In the water closet force the rubber plunger down through the bowl into the trap, then draw up and down as a churn. To force out small waste-pipes, such as bathtubs, wash bowls, sinks and urinals: First, fill bowl partly full of water, then place the rubber plunger over the mouth of the pipe and force down on the handle hard and fast until the stoppage is removed. Do not lift rubber clear of the bottom of the bowl. Use only the elasticity or spring of the rubber. The overflow holes or other vents should be stopped up so that full pressure may reach the obstruction.

STEAM PRESSURES FOR STEAM HOSE.

Standard grades of Commercial Steam Hose, of whatever ply, are not guaranteed to withstand any temperature beyond that due to steam under 40 to 50 lbs. pressure. Where this is exceeded a special brand of hose will be supplied which, on account of its superior quality, carries a higher price than the standard or stock article. This hose can be furnished for duty up to 200 lbs. steam pressure, and while it is not guaranteed as to time of service, it will be replaced in the event of failure, through defect, after a reasonable trial.

HALL'S IMPROVED PIPE WRENCH.

It is quickly adjusted to different sizes of Pipe, and grips, quickly and firmly, galvanized as well as other Pipe. It releases instantly, and cannot lock on the Pipe.

Having only one gripping point it mars the Pipe less, and acts more like the old Pipe Tongs than any other Wrench.

It can be easily sharpened on any grindstone or emery wheel, without taking apart.

It has no springs or other parts to break or get out of order.

The jaws are smooth and parallel, and will not mar a nut or highly polished fittings.

When used with Hall's Elastic Pipe Clamps, it will grip the thinnest and most highly polished Pipe or Tubing without marking or crushing it.

Length Open.....Inches,	6	10	14	18	24

No. 4 " 18 " "	19.00		
No. 5 " 24 " "	23.00		

SMITH'S PATENT RATCHET.

By removing the cap "A" the stock may be instantly removed, and the entire tool taken apart; or, when a Boiler Ratchet is required, a short stock "B," as shown, can be substituted for the long one, and thus the necessity of having two Ratchets is avoided. The working parts being entirely enclosed, no dirt or chips can enter gears, and the tool can be kept thoroughly oiled at all times without fear of clogging up.

Each Ratchet is fitted with two Socket Bushings, one for square shank Drills and one round to fit shank of a No. 2 Morse Twist Drill.

No. 1, 12 inch Lever.....	\$13.50	BOILER RATCHETS.	
No. 2, 15 " "	16.00	No. 1, 12 inch Lever.....	\$9.00

Extra Short Stocks, for Boiler Work, for either 12 or 15 inch.....\$6.00

KEYSTONE RATCHET DRILL, REVERSIBLE.

Cut shows Ratchet Drill, adjusted, for square shank drills, cut "A"; also other parts for drilling purposes, all parts being interchangeable in holder. "C" represents socket for Morse taper shank drills, and "D" is a sleeve fitted to Morse taper socket and in which square shank drills may be used. "B" represents Boiler Makers' Drill for square shank. "F" indicates the knob for reversing the movement of ratchet. "E" indicates the cap by which the various sockets are held. The Feed Nut, shown in cut "A," is used also with Morse taper shank drill socket "C," and with which a novel and unique method is employed for dislodging the drill or sleeve from the socket.

THE HALL TAPPING MACHINE.

FOR TAPPING WATER OR GAS MAINS
UNDER PRESSURE.

This machine is simple, durable, strong, well made, free from valves and complications, and all parts are interchangeable. It will stand any pressure and take almost any style of service cock, avoiding the necessity of using a special make and having the usefulness of the machine depend upon the supply at hand.

One machine taps sizes from $\frac{1}{2}$ to $1\frac{1}{4}$ inches and can be used equally well on mains of any size from 4 to 24 inch by simply changing the rubber form which is placed between the machine and main.

Machine for $\frac{1}{2}$, $\frac{5}{8}$, $\frac{3}{4}$ and 1 inch cocks, with Drill-Taps, Mandrels, Wrenches, Ratchet, and rubbers, for 4 to 16 inch mains.....\$80.00

CLIMAX RATCHET STOCK.

A PIPE STOCK WITH PIPE VISE ATTACHMENT.

The great difficulty and inconvenience of threading iron pipe in ditches, under floors, in corners, overhead, &c., are so well known to all who have attempted it that a tool which will do this work quickly and conveniently will be promptly appreciated.

With this tool it is not necessary to dig up or take out whole lengths of pipe; the defective part of pipe can be cut out and the threads cut on the pieces in the ground with the greatest ease and convenience, not only saving time, but avoiding much unnecessary and disagreeable work.

OPERATION.—Slip the tool on the pipe to be threaded until the end of the pipe comes in contact with the die, then screw up the Vise handle, at the end of which is a strong vise to grip firmly the pipe, and rotate the ratchet-handle, which revolves the die and by means of the leading thread carries the die on the pipe, producing a true thread; after cutting the thread, by reversing the pawl and moving the handle reversely the die runs off the pipe.

No. 1 Threads $\frac{1}{4}$ to 1 inch Pipe, takes Die	
2, $2\frac{3}{8}$ and $2\frac{1}{2}$ inches square	\$10.00
No. 2 Threads 1 to 2 inch Pipe, takes Die	
$2\frac{3}{8}$, $2\frac{1}{2}$, 3, $3\frac{7}{8}$ and 4 inches square	17.00
Pipe Dies, $2\frac{3}{8}$ inches square	2.00
3 "	3.50

This stock is attractively finished in Nickel and Japan, and every one is shipped in a strong wooden box.

" 13½A	" 600 " 40.00	" 13½AA	" 600 " 42.00

These Barrows can be furnished with one wheel. All parts are interchangeable.

BUFFALO PORTABLE FORGES.

FORGE No. 1.

The forges with closed hoods are strongly made of sheet iron, completely enclosing the fire-place, and are fitted with a large sliding door in front and small one in rear, for manipulating fire, etc. Thus equipped, the escape of sparks, fumes and smoke is prevented, and adapts them for use in annealing and refining metals, and in planing mills, furniture factories, saw-mills, oil refineries, sugar works, etc.

Half open hood; height, 29 inches; fan, 10 inches; hearth, 21 x 27 inches; weight 140 pounds.

Price, - \$40.00

FORGE No. 4.

No. 4 will produce a welding heat on iron $1\frac{1}{2}$ in. in diameter in 5 minutes, and do heavier work if required; but on account of size of fireplace and general capacity, is specially recommended for use of die sinkers, model and tool makers, plumbers, tinsmiths, jewelers, dentists, locksmiths and small hardware manufacturers, for heating and tempering tools of all kinds.

Half-open hood; height, 33 inches; size of hearth, 18 inches diameter; weight 75 pounds.

Price, - \$27.00

HAND AND POWER GRIND STONES.

Knocked down for export when required.

YALE-WESTON TRIPLEX CHAIN HOIST.

This is without question the most efficient block now made. 80 per cent. of applied power is utilized in lifting the load. TRIPLE POWER.

TRIPLE SPEED.

TRIPLE DURABILITY.

Direct Form without Lower Block. 1 to 2 Tons.

This means that in this block *only 20 per cent.* of the operator's labor is wasted in overcoming friction.

INCREASED WEARING SURFACE,
SUBDIVISION OF STRAINS,
LOAD ACCURATELY EQUALIZED,

among the great advantages obtained in this block.

Type A with One Upper Hook. 3 to 10 Tons.

CAPACITY. in Tons	Price Comp'ete.	*Hoist in Feet	Extra Hoist Price Per Foot.	Minimum Distance be- tween Hooks in inches.	† Reach.	Net Weight in Lbs.	‡ CHAIN PULL.

* NOTE. - Figures denote height in feet which blocks, with regular lengths of chain, will hoist from level on which operator stands.

THE YALE-WESTON DIFFERENTIAL BLOCK

This is the most simple form of Chain Block on the Market ; is
a powerful hoist, designed particularly for general
and rough usage.

Capacity in Tons.	Price Complete.	*Hoist in Feet.	†Extra Hoist Price per Foot.	Minimum Distance between Hooks.	Net Weight in Lbs.	‡Chain Pull.	
						Pounds.	Feet.

* Figures denote height in feet which blocks, with regular lengths of chain, will hoist above level on which operator stands.

† Each additional foot of hoist requires 4 feet of additional chain.

‡ Figures denote the pull in pounds required to lift the full load, and the number of feet of chain which must be handled to lift the load one foot.

YALE DUPLEX CONVERTIBLE SCREW BLOCK.

In this block is found the latest improvements of the
Screw hoist.

HIGHEST EFFICIENCY, ABSOLUTE SECURITY,
CONVERTIBLE

to dispatch lowering. Lightest weight hoist of
the screw type on the market.

* Figures denote height in feet which blocks, with regular lengths of chain, will hoist from level on which operator stands.

‡ Figures denote the pull in pounds required to lift the full load and the number of feet of hand chain which must be handled to lift the load one foot.

DUDGEON'S LATEST IMPROVED HYDRAULIC JACKS.

This Jack appears to the eye when depressed a simple Cylinder, with a Base and Head, when elevated one Cylinder sliding within another. To the inner one (which is termed the Ram) is attached the Head having a Socket to receive the Lever which operates the Force Pump in the lower end of the Ram; the remaining space is the reservoir containing the liquid which when forced into the lower chamber causes the Ram to rise, and to lower, when allowed to return through the lower valve and back passages operated by the same lever. These Jacks are light, portable and easy of application, worked by one man who can lift 10 tons, 1 foot in 1½ minutes or 20 tons in three minutes and so on proportionately.

they answer for any thickness of Tube Sheet.

HORIZONTAL

TUBULAR BOILERS.

FULL-ARCH FRONT SETTING.

These Boilers are built of Flange Steel 60,000 lbs. T. S.

FIXTURES FOR FULL-ARCH FRONT BOILER:—These comprise Front complete, with Liners for Fire Brick, Grates, Grate Bearers, Rear Arch Bars, Rear Ash Door and Frame, two Wall Plates with Rollers, Oval Stack Plate, Binder Bars and Cross Rods, Anchor Rods for Front, Safety Valve, Steam Gauge, Water Gauge fitted with Stand Pipe, three Gauge Cocks with Pipes, Whistle and Pipe, Blow-off Valve, Check and Stop Valves, Smoke Stack and Guys (four times the length of Stack).

Anything called for and not in above list will be charged as an extra.

“MONTAUK” VERTICAL ENGINE.

These Engines are self-contained, cannot get out of line, and require no foundation. They are built under careful supervision, and tested under steam before shipment. All wearing parts of ample size and well fitted. Crank shaft, piston rod, valve stem, crank and wrist pins and connecting rod of steel. Crosshead fitted with large brass gibs and instantly adjustable. Each Engine is fitted with governor, throttle valve, drip cocks, sight feed lubricator, wrenches and oil cups, making it a HIGH GRADE ENGINE FOR CONTINUOUS DUTY.

PAT. CALENDERED IRON AND STEEL SHAFTING,

CUT BY LATHE TO ANY LENGTH DESIRED (DOWN TO ONE FOOT)

WITHOUT EXTRA CHARGE.

In designating lengths of shafts, when the lengths are composed of feet alone, or inches alone, the use of the signs 'and' and 'in' place of the words "ft." and "in." is advised against, as a slight blur in copying will often render it difficult to determine which sign was used by the writer of the order.

Actual diameters wanted should be specified, as we manufacture "net" sizes as well as what are generally termed "turned shafting standards." For example, $1\frac{1}{8}$ shafting is frequently called 2 in. shafting because made from 2 in. round iron. Both sizes are made by us, hence a customer ordering a "2 in. shaft" from us would receive a shaft measuring exactly two inches in diameter, which would be one sixteenth of an inch too large if a turned shafting manufacturer's "2 in." (actual size $1\frac{1}{8}$) was the size required.

Orders are frequently tendered to us for lines of shafting without the length of each shaft being specified. In other words, lengths at our option. This should not be done when the hangers must be located at certain specified points; that is, it should only be done when the hangers can be supported at any points that the locations of the couplings may necessitate.

Location of pulley or other special keyseats should be shown by sketch. In addition it should be designated which shafts are to be keyseated upon both ends for couplings, and which upon one end only.

All shafts containing pulley or other special keyseats should be tested after the keyseating has been finished, and restraightened if necessary. This applies alike to turned shafts and calendered shafts.

We are equipped for cutting keyseats in shafting, and also straightening facilities. Therefore, all shafts, whether keyseated or plain, are guaranteed perfectly straight.

PRICE LIST OF FINISHED SHAFTING.

Cut to length from 1 foot to 24 feet, inclusive.

GILBERT
WOOD SPLIT PULLEYS.

IN ORDERING PULLEYS, please state:
1st, Style. 2d, Diameter. 3d, Width of Face.
4th, Exact Size of Shaft. 5th, Kind of Face
(Crown or Flat). UNLESS OTHERWISE SPEC-
IFIED, Crown Face will be sent.

STYLE B PULLEY (12 in. and larger).

WIDTH OF FACE (IN INCHES).

STYLE C PULLEY (3 to 14 inches).

DIAM. Inches.	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25

ADJUSTABLE DOUBLE BRACED SELF-OILING HANGER.

WITH BABBITTED BOXES. (INTERCHANGEABLE)

VARIABLE DROP.

(1½ to 2 inch range.)

Construction such as to permit of quick adjustment to any drops that may be desired within the range specified.

SECTIONAL VIEWS OF BOXES.

Before placing shafting in position, oil chambers should be filled with oil nearly to level of bottom of shaft, and should be cleaned out and refilled with fresh oil every three to six months, according to speed at which shafting runs.

Range of Drop in Ins.	6 to 8	8½ to 10	10½ to 12	12½ to 14	14½ to 16	16½ to 18	18½ to 20	20½ to 22	Length of Bearing. Inches.

JUDSON GOVERNORS.

In these Governors the spiral springs are reliable and insure accurate and durable spring action. By removing one spring the engine speed can be greatly reduced, allowing full throw of Governor under all conditions of engine load. In case of accident to one spring the Governor will operate until the spring can be replaced.

For convenience in ordering, the Governors are described in two classes—A and B. Workmanship and quality the same. Class A, either Standard or Spring Governor, with Automatic Stop Motion Spring, Speeder and Sawyer's Lever. Class B, same as class A, except without Automatic Stop Motion.

List Prices same as above.

Class A.—Spring. (High Speed).

Class B.—Spring. (High Speed).

WATERS' GOVERNOR.

The Waters' Governor has now been in use about thirty years, and has steadily grown in favor since its introduction; the sales have largely increased, and the Governor has been kept up to the high standard of excellence for which it has long been noted. By the theory embodied in its design, it is not affected by the action of gravity, the weights remaining always on the same plane, and as they are supported by the springs which furnish the centripetal force, there is consequently no friction in the joints of the ball arms, they merely serving as levers to operate the valve. Having a valve of large area, greatly in excess of the steam pipe, and being quick acting and sensitive, insures the highest economical results, as well as closeness in regulation.

The method of adjusting the speed of the Governor to the requirements of the engine is very convenient. The valves and seats are of composition, which does not rust or corrode. The perfect system of interchangeability of parts greatly facilitates and cheapens the cost of repairs. On account of these features, it is particularly adapted to places where changes are sudden and severe.

List Prices same as above.

KELLAM'S DAMPER REGULATOR.

The KELLAM has been a favorite "up to date" machine for several years and has had a very large sale. It is made in two sizes and can be used on any boiler pressure.

No 1.....\$150.00

For dampers 4 feet or over.

No 3.....\$125.00

For dampers up to 4 feet.

LAWRENCE HYDRAULIC DAMPER REGULATOR

is conceded to be one of the most complete Machines of its kind, as it embodies all the improvements to insure perfect accuracy.

The steam weigher rests on an iron base, and the lever directly operates the water valve, and there is no lost motion.

The water motor being double acting, there is no necessity of having any weights on top of piston. The water valve is fed through a mud-drum which prevents any dirt reaching the water motor; the diaphragm is covered with cool water which keeps it always flexible.

Will control one or more Dampers as required.

Very Sensitive and Powerful, making a partial stroke in both directions by water pressure.

Easy to repair, and Simple in Construction.

Manufactured under the Locke Patents, Complete, Each.....\$100.00

CLIMAX DAMPER REGULATOR.

The damper in the flue is closed by the downward motion of the piston, and it is therefore necessary to apply sufficient weight to the damper level to cause it to open the damper, and at the same time pull up the piston, which it will do immediately after a slight reduction in the steam pressure, which causes a downward movement of the diaphragm casing, and a corresponding movement in the valve, whereby the inlet port is closed and the exhaust port opened, which allows the water in the cylinder to escape, thus enabling the weight on the damper lever to open the damper, and at the same time pull up the piston. In this position the damper will remain until the steam pressure increases slightly, which causes an upward motion of the diaphragm casing, the corresponding motion in the valve causing the exhaust port to close and the inlet port to open through which the water enters the cylinder and drives the piston down, thereby closing the damper.

NASON'S DAMPER REGULATOR, WITH SAFETY ATTACHMENT.

P A T E N T E D 2d M A R C H, 1886.

Nearly all low pressure heating apparatus are controlled automatically by means of a regulator consisting of a flexible diaphragm made of rubber, which is a perishable material, likely to crack after being used a comparatively short time, and finally to rupture when some trifling excess of pressure beyond what has commonly been used is applied to it.

When this does occur it is self-evident that the diaphragm, together with the post and lever above it, will at once drop to the same position as that in which they stand when there is no pressure on the boiler, the effect of which is to close the air door above the fire and to open the ash-pit door to its fullest extent.

The boiler at once "runs away," and if there is no one fortunately at hand to reverse the position of the doors and check the fire the consequences are likely to be serious, the least evil being that of blowing out the water through the safety valve and burning the boiler.

Such an accident is most likely to take place at the very time that the results are likely to be the most harmful ; that is, when there is a large fire, with the furnace full of burning coal.

Occurring, as is very possible, during a cold night, when all the household are asleep, the consequences can be imagined.

To avoid such accidents, the Nason Regulator, with Safety Attachment, patented 2d March, 1886, has been designed and is offered to the Trade with the confident assurance that when appreciated, no prudent or careful steam fitter will construct a low pressure boiler without using this Regulator, as with it such an accident as described above is impossible.

The attachment is constructed as follows :

Into the chamber of the Regulator, but above the diaphragm, is tapped a piece of $\frac{3}{8}$ -inch pipe, which extends laterally out as far as the lever to which the chain of the ash-pit door is usually attached.

The pipe terminates in a fitting of peculiar shape containing a slot through which slides a link of fusible metal—the latter being attached to and forming a part of the door chain.

In the event of the bursting of the diaphragm it is relieved of pressure and the lower door opens, but as the hot water and steam pass through the rupture they are at once conducted through the $\frac{3}{8}$ -inch pipe to the link, which, instantly melting, parts the chain, drops the door and checks the fire.

The cost is so little beyond that of ordinary regulators, when compared with the whole cost of an apparatus, as to form no excuse for not applying the Nason Regulator.

All links are carefully made of an express alloy, which we guarantee to melt at 160° F.

With each regulator an extra link is furnished.

The attachment can be applied to all diaphragm regulators in use on the latter being sent to us.

PRICES, WITH SAFETY ATTACHMENT.

BALTIMORE OIL CANS.

The tops are galvanized, the bodies kalamined (that is, coated with spelter and lead, lead preponderating), making them last longer and less liable to rust than if all spelter (galvanizing) were used.

The bodies and bottoms are corrugated and united in such a manner as to give the greatest strength and durability.

SWEET'S EXHAUST HEAD.

The accompanying cut shows a Sweet's Direct Exhaust Head, which is constructed upon a principle that has been demonstrated by years of use to give absolute separation. The steam enters to the inner side of an inverted cup, and, as it passes downward between the sides of the inlet pipe and the cup, is brought in contact with a peculiarly perforated lining which quickly separates and traps the little particles of water and oil. As the area is ample the current of steam can be made thin, so that nearly all of it comes in contact with the lining, and most of the water and oil removed this way, but any that may remain is thrown to the water chamber by the quick reversing of the direction of steam current as it passes up and out of head. Tubes are provided to convey any moisture caught on the covers to the water chamber; tubes are also provided to conduct the oil and moisture caught by the lining above-mentioned to the water chamber; in fact, the principle followed throughout is to completely remove separated particles from further contact with steam. The Heads are made heavy and strong and fully guaranteed by the makers in every way.

THE NASON STEAM TRAPS.

THE "NASON" TRAPS.

..o-o-o..

(Size No. 1.)

For Pressures of 80 lbs. or less

THE "SIDELUG" TRAPS.

(Patented)

(Size No. 1.)

For Pressures ranging from 80 to 150 lbs.

PLEASE READ THIS.

The steam traps manufactured by the Nason Manufacturing Company have always enjoyed the reputation of being the best of their kind—more extensively known and used than any other—in fact the standard of excellence with steam-fitters and engineers in all parts of the country.

Following the demand made by modern steam engineering for higher pressures, it has been thought judicious to divide the Nason traps into two groups, one for ordinary working steam pressures of 80 lbs. and less; the other for pressures above 80 and less than 150 lbs. For the lower pressures no change of design has been made, the high standard of construction and good workmanship being, as in the past, fully maintained; these traps will continue to be known and specified as the NASON steam trap.

THE "NASON" TRAPS.

(Sizes No. 4 and 5.)

For higher pressures a radical departure in construction of the covers has been designed and patented, consisting of so reinforcing the joints at the point of inlet and outlet where the steam ports pass from pots to covers, that leaks near these places cannot occur, there being no possibility of the gaskets blowing out. A considerable increase in the number of bolts used for each size has been adopted, thus rendering these traps not only amply equal to the extreme work imposed upon them, but infinitely better than anything hitherto made in this class of trap. These traps are known as the Nason "SIDELUG" trap, and should be universally specified in all cases where they are to be used in connection with pressures exceeding 80 lbs.

For facility of access to the sleeve

THE "SIDELUG" TRAP.

(Patented.)

(Sizes Nos. 4 and 5.)

seats and sleeves, the two larger sizes (Nos. 4 and 5) are fitted with hand-hole plates on the covers, which permits of readily getting at the working parts without breaking the main joint.

CONSTRUCTION

OF THE NASON AND SIDELUG TRAPS.

Reference to the sectional cut shows the construction of the Nason traps as follows :

A cast-iron reservoir or pot closed with a cover provided with two cored passages, contains a float which is fitted with a spindle for its guidance. A housing or sleeve is screwed centrally into the under side of the cover and within it the float spindle slides smoothly, permitting a short vertical motion. The top of the float-spindle is ground flat, and its upward movement is arrested by coming in contact with a bronze plug having a

central opening, the two surfaces thus constituting a discharge valve for these traps.

One of the cored passages in the cover alluded to is for the discharge of water from the traps after passing through the main valve, and the other serves as a by-pass, to permit any large volume of air or water to be blown through, when starting, without going through the cylinder and discharge valve. A valve located externally in the cover gives entire control of this action.

SECTION

Showing the interior of the "Nason" and "Sidelug" traps with names of parts. If new Portions are at any time wanted they should be ordered by the names as given.

OPERATION.

Care being taken that the Traps are in all cases placed below the surface from which water of condensation flows, the discharge enters at the point marked "Inlet," and passing through the hole "A" into the body of the Traps, a Diaphragm above the float diverts the water of condensation into the pot, where, gradually rising, it first raises the float, thereby closing the discharge valve, and then after reaching the top of the float it flows into it. When the float has nearly filled, its weight becomes such that it overcomes the tendency of the discharge valve to remain closed, being held there by steam pressure, and the float drops to the bottom, thereby opening the valve. Acting on the surface of the water, the steam pressure immediately drives it up through the sleeve, discharge valve, and thence by way of the cored passage to the outlet.

When the float has been thus nearly emptied it becomes so light that it is again raised by the water about it, thus closing the valve, and the operation repeats itself.

This action it will be seen is purposely intermittent; which necessitates that the valve shall be either wide open or completely closed, an advantage which entirely obviates the "wire drawing" process to which all other traps of the ball-cock style are subject. The life of the valve is thus prolonged, and it remains tight for a much longer period than it otherwise would.

As will be seen, the Nason and Sidelug Traps have no motive power within themselves, and they are not Return Traps; water must run into them by gravitation, and the discharge from them should preferably be into the open air or a hot-well.

Under certain conditions the discharge may be considerably elevated above the level of the Traps, such lift being fixed by the amount of steam pressure to which it is connected; but in these cases an automatic appliance for removing air which accumulates between the steam surface and the Traps must be provided, and such service is not recommended.

PLEASE NOTE.—In ordering either NASON or SIDELUG Traps it is important that the steam pressure under which they are to be used should be stated, in order that the sleeve seat valves shall be of a size which is adapted to the duty.

All traps issued by us are tagged and marked with the pressures for which their sleeve valves are fitted. If used for higher pressure than that stated on the tag, failure of operation may result, for which we are in no way responsible.

The following table shows the number of square feet of heating surface in a common high pressure Steam Heating Apparatus, which Traps of the several sizes may be expected to relieve under ordinary exposure to cooling:

NUMBER OF STEAM TRAP.....	1	2	3	4	5
Size of Pipe Connections.....inch	$\frac{1}{2}$	$\frac{3}{4}$	1	$1\frac{1}{4}$	$1\frac{1}{2}$

Weight, lbs. "Nason".....	40	80	113	176	336
Weight, lbs. "Sidelug".....	47	92	125	212	343
Price, "Nason".....	\$16.00	\$20.00	\$27.50	\$42.50	\$70.00
Price, "Sidelug".....	16.85	21.30	29.25	45.50	74.75

For indirect Steam Heating Apparatus the size of the Trap used should be at least 40 per cent. larger than that given in the table, and if the coils are under the action of a blast from a fan or blower the size of Trap must be still further largely increased.

For special service, such as separators, vacuum pans, slashers, or for steam coils immersed in water, the number of square feet given in the table cannot be taken as an index of the size to be used. The amount of water to be discharged must be otherwise estimated, preferably by weighing the amount collected per minute, and the size selected by this method from the table.

DIRECTIONS FOR USING THE "NASON" AND "SIDELUG" STEAM TRAPS.

FIRST.—Be sure that the Trap is not to be used for higher pressure than that marked on its tag.

SECOND.—Screw the valve bonnet which accompanies the trap into the hole on top, being careful that before doing so the spindle is backed out as far as possible, in order to avoid crushing the seat on the disc.

THIRD.—Place the Trap in all cases below the lowest point which is to be drained.

FOURTH.—Connect the drip pipe from end of coils of apparatus to the opening marked "Inlet."

FIFTH.—Open the valve on top for a few minutes to allow the air or excess of water coming from the apparatus to escape.

SIXTH.—When the steam begins to flow in considerable quantity close the valve tight and allow it to remain so while the trap is in operation. If while the pressure is on the coils, they become cold or water stops escaping from the trap, it is usually due to an accumulation of air. In this case open the valve a few minutes to allow it to escape, and then again close it.

SEVENTH.—The trap is tested and guaranteed to work up to the pressure marked on its tag. If more, or much less, are required, it should be so specified, in order that the valve may be adapted to such requirements.

EIGHTH.—This trap will discharge water from its outlet a few feet above the elevation on which it is placed—depending on the pressure; but it will NOT RETURN WATER TO THE BOILER—not being made for this purpose.

NINTH.—If the apparatus or trap is to be left inoperative at any time when the temperature is likely to go below the freezing point, remove the plug at the bottom, in order to allow the water contained in it to escape, and thus avoid damage to trap.

This trap is guaranteed only to drain the number of square feet specified in our table, when the surface consists of Radiators, Wall Coils, or similar surface, acting only on the direct system.

If connected to a heating apparatus on the indirect system, a trap 40 per cent. larger should be used. If connected to Sugar Pans, Evaporators, Separators, or apparatus where the heating surface is under water, the condensation is much more rapid, and surface, as named in our table, is not to be used as giving the capacity of the trap. For exceptional work, we will name special sizes and prices for traps to be used.

SERVICE TO WHICH THEY MAY BE APPLIED.

For taking off the water of condensation for Steam Pipes and Coils, and apparatus employed in Steam Heating.

For draining Steam Kettles, Vacuum Pans, Mash Kettles, Steam Engine Supply Pipes, and Separators, and keeping Cylinders free from water; Evaporating Pans, Steam Jackets on Engines, Steam Jackets on Pumps, Stills in Absorption Ice Machinery, etc., etc.

These traps are recommended for any service requiring the removal of water of condensation without the escape of steam accompanying it.

A large assortment of standard sizes is kept in stock, which can be modified to suit any usual condition of service by changing their discharge valves, an operation only requiring a few minutes, and orders are thus usually filled on the date of their receipt.

PLEASE NOTE.—All traps manufactured by us bear the name "NASON M'FG CO.," on the cover, and customers are requested to insist on this mark, as several inferior and light imitations are on the market and sold as our trap, which are giving general dissatisfaction, and causing prejudice against those of our make. Again we say,

AVOID SUBSTITUTION.

THE CHAMPION RETURN STEAM TRAP AND BOILER FEEDER.

For returning condensation to Boilers from Steam Heaters of all kinds, Drying Cylinders, Evaporating Pans, Brewing Kettles, Paper Dryers, etc., whether above or below the Boiler.

The Champion Return Steam Trap and Boiler Feeder is operated by the buoyancy of a Cast Iron Ball, alternately surrounded by water, and connected by a spindle to a lever on the outside, thereby operating a steam and exhaust valve both in one chamber, and placed on top of the Trap in such a position as to exhaust freely when desired, and reduce the pressure so as to enable the Trap to take water immediately and prevent it from becoming air bound. The Trap will also take condensation from two or more return pipes, on some of which the pressure may be as low as five pounds and others as high as one hundred pounds, without causing the least obstruction to the return pipe upon which the pressure is low. This Trap is in operation in a large number of buildings in New York and elsewhere.

Receivers	10.00,	16.00,	24.00 and	40.00
Outlets of Receivers	1 in.	1¼ in.	1½ in.	2½ in.

DIRECTIONS FOR CONNECTING TRAP.

1. Always take steam direct from boiler.
2. Always place trap at least from 2½ to 3 feet above the water level of boiler.
3. Always connect discharge pipe from trap to boiler, independent of any other discharge.
4. Always place receiver below the lowest radiator.
5. Place ball on lever just far enough out so as to let the float come to the bottom when trap is empty.
6. Never reduce steam pipe leading from boiler to trap.
7. Never use lead when making joints or connections.
8. It will be necessary to set up two or three different times on flange-bolts, when trap becomes cold.
9. I would advise the use of swing checks, as giving better results.
10. Always place trap so that it can easily be got at, and have the gear in front.
11. Always be careful not to deviate too much from the style and mode of connection as illustrated in cut.
12. When everything is connected, before starting trap, compare with directions to make sure that everything is as it should be.

TYPES "C" AND "A."

Type "C" is made in the *upright* and Type "A" in the *horizontal* pattern; both being identical in construction and efficiency and corresponding sizes having the same capacities. Each and every corresponding part of both Types is *interchangeable* with the exception of the Body.

These Inspirators will work with steam pressures of from 25 to 200 lbs. and higher, *without any adjustment* of either steam or water supply, and will work water at a temperature of 120° Fahr.

Type "C."

STYLE A.

DOUBLE OR JACKET STEAM KETTLE.

In this Kettle the inner Caldrion is flanged at the top to the body or Kettle proper—the interstitial space forming the Steam Chamber and heating surface.

It is furnished with Copper or Iron Caldrions and with or without covers.

STYLE B.

SEAMLESS JACKET STEAM KETTLE

These Kettles are all cast in one piece, having a steam space cored out. They do not require either Bolts or packing in their construction, and are proved at a steam pressure of 75 pounds. Covers of Black or Galvanized Iron and Planished Copper, also larger sized Kettles made to order.

STYLE C.—These kettles are tested under 130 to 150 lbs. pressure. They are cast in one piece, and are entirely without joints. Supplied with outlet or draw-off at bottom if desired, at extra cost of \$1.50 and upward, according to design.

Kettles will be furnished without draw-off, unless otherwise ordered.

STYLE D.

STYLE D.—Each kettle is fitted with a bottom outlet for drawing off the contents. The outlet is covered by a removable strainer. The outer casing or jacket forms a substantial support for the kettle and prevents, in a measure, loss of heat in the room. The steam chambers are tested at about 80 lbs., and can be tested for higher duty if required.

Illustration shows C-shaped steam chamber and location of inlet and outlet. Kettles cast in one piece—without joints.

BUFFALO STEEL PRESSURE BLOWERS.

FOR CUPOLA AND FORGE FIRES, AND OTHER HIGH PRESSURE DUTY.

The special features of this Blower are: long, heavy journals in standard ratio of length to diameter of 6 to 1, the solid shell being cast in one piece, and fewer parts than in any other machine; under any service the bearings being in perfect alignment vertically and laterally with the rest of the machine, making it far superior as to durability, smooth running, and economy of power, than any other make.

WORTHINGTON STEAM PUMPS.

WORTHINGTON BOILER FEED PUMP, PISTON PATTERN, GOOD FOR 150 LBS. PRESSURE.

These pumps are fitted with packed water pistons of iron or brass, as may be required, operating in brass-lined cylinders. The water valves are of brass or hard composition, and are controlled by brass cylindrical springs, held in place by guards of the same material.

Diameter of Steam Cylinders.	Diameter of Water Pistons.	Length of Stroke.	Horse Power of Boiler, based on 30 pounds of water per hour, which the pump will supply with ease.	Diameter of Pistons required in any single cylinder pump to do the same work at same speed.	SIZES OF PIPES FOR SHORT LENGTHS. To be increas- ed as length increases.				List Prices.
					Steam Pipe.	Exhaust Pipe.	Suction Pipe.	Discharge Pipe.

A slight additional charge is made when Pumps are fitted with Brass Plungers and Piston Rods. An extra charge is also made for Bed-plates.

To designate the sizes, give the diameters of Steam Cylinders and Water Plungers, and length of stroke.

Plunger and Ring Pattern Pumps for General Service, in sizes larger than above, will be quoted on application.

THE SNOW “DUPLIX PLUNGER” PUMP.
FOR GENERAL SERVICE.

The engraving represents the standard design for Duplex Steam Pumps. It is intended for all service when the requirements do not exceed a working pressure of 150 lbs. per square inch. These pumps are fitted with two double-acting plungers, rubber valves, brass seats, guards and springs, suitable for pumping hot or cold water.

Metal valves, with special seats and guards, can be furnished to suit any particular requirement. In emergency the capacities given below may be considerably increased. In comparing the capacities of pumps, it should be borne in mind that the Snow Pump has *two* plungers and is therefore double the capacity of a single cylinder pump of the same dimensions.

Size, 12 x 8½ x 12.

Diameter of Steam Cylinders.	Diameter of Water Plungers.	Length of Stroke.	Displacement in Gallons per stroke of ONE Plunger.	Proper Strokes per minute of ONE Plunger, varying with kind of work and pressure.	Gallons delivered per minute by BOTH Plungers at stated number of Strokes.	Diameter of Plunger required in any single cylinder pump to do same work at same speed.	Diameter of Pipes in Inches.				List Prices.

Sizes are designated by the diameter of the steam cylinders, the diameter of the water plunger, and the length of stroke.

Any number of combinations in addition to the above list can be supplied to meet the requirements of any service.

Bed-plates extra. When pumps are fitted with brass plungers and piston rods, a slight extra charge is made.

THE DEANE AUTOMATIC DUPLEX FEED PUMP AND RECEIVER.

Size 6—4—6. Pump.

This apparatus is designed to automatically drain heating systems and machines or appliances used in manufacturing which depend upon a free circulation of steam for their efficiency. It furthermore is arranged to automatically pump the water of condensation drained from such systems back to the boilers without loss of heat.

The automatic action of the pump and its speed are controlled by a bucket in receiver which depends upon the principle of specific gravity for its operation. It is connected directly, without the use of intervening levers, cranks and stuffing boxes, to a governor valve in steam supply pipe to pump, thus making the action of the pump conditional upon the rise and fall of the bucket in the Receiver.

The economy resulting from its use is unquestionable, and the satisfactory and increasing use of this machine leaves no doubt as to its efficiency.

WORTHINGTON AUTOMATIC FEED PUMP
AND RECEIVER.
PATENTED.

The main difficulty met with in any attempt to design a device for automatically controlling the speed of a pump through the level of water in a tank is to secure a reliable form of float. It has been found practically impossible to make a hollow float that will stand water pressure and remain tight ; so that in the place of the air-tight copper balls, formerly used so extensively, various forms of displacement floats depending upon counterbalance weights to make them operative are now employed.

The automatic arrangement illustrated herewith is believed to be freer from all the defects common to this class of apparatus than any heretofore devised. A float of copper is provided with a hole in the top through which the water as it enters the tank is allowed to flow until the float is entirely filled. Its weight, when filled with water, is counterbalanced by a iron weight secured on the opposite end of the beam. As the float is an open one, the pressure of course is equal on the inside and out, so that there is no tendency to collapse. The rising and falling of this float, depending upon the level of the water in the tank, operates a balanced valve which controls the admission of steam to the pump. The stem of this valve passes through a stuffing box located within the tank, any leakage from which is caught by the tank, and is thus unobjectionable. As this stem has no work to perform except to move the balanced valve, it is of small diameter and its stuffing box so insignificant in size that even should the packing tend to stick on the stem, it could not exert friction enough to interfere in any way with the function of the float.

The Worthington Automatic Feed Pump and Receiver is made in four sizes, according to the following list :

No.	Size.	Amount of Radiating Surface it will Drain.	APPROXIMATE DIMENSIONS.			List.
			Length.	Width.	Height.	
1	3 x 2 x 3	5,000 square feet.	3 ft. 1 in.	2 ft. 6 in.	23½ in.	\$300.00
2	4½ x 2¾ x 4	12,500 " "	3 " 3 "	2 " 9½ "	23½ "	380.00
3	5¼ x 3½ x 5	25,000 " "	3 " 9 "	3 " "	23½ "	440.00
4	6 x 4 x 6	40,000 " "	4 " 2 "	3 " ½ "	23½ "	480.00

We can also supply these receivers for use in connection with electric pumps, automatically controlled, if desired.

Each.....\$13.00 \$16.00

Brass, Single Acting Lift and Force Pump.

NASON'S BOILER FEED PUMP.

The cut represents our Special Pump for boiler feeding, and for raising water when desired, against high pressures.

It is to be driven by a crank, and by placing the driving pin, to which the pump rod is connected, at a greater or lesser distance from the center of the shaft, the quantity per minute can be regulated to a nicety.

The pump is of the plunger pattern, the rod going down into the inside of the plunger, and it is connected at the bottom of it by means of a ball joint, which admits of free motion in all directions, thus reducing any wear on the surface of the plunger to a minimum.

It will be noticed that the gland and stuffing box are made of very liberal size, with a large movement for the follower, so that the pump requires but little attention to the packing; and it will never be found necessary to screw the follower down hard.

VALVE INDICATOR POST.

This Indicator Post is designed expressly for water valves connected with street mains, and for use with valves for fire service in mill and factory yards.

This Indicator shows plainly at a glance whether valve is open or closed.

Serious fire damage has often occurred by reason of valve being closed and water accidentally shut off from automatic sprinklers, and continuing shut off unknown to the superintendent or others in charge.

By using the Indicator Post you do away with the annoyance and delay of searching for a flush gate box sometimes hidden under snow or dirt, and the delay of opening a frozen gate-box cover.

Turning the nut N opens and closes the valve, thereby raising or lowering the brass band T, which is carried around post. This band covers and uncovers the words OPEN or SHUT on both sides, and will positively indicate whether valve is whole or partly open or closed.

The moving parts and letters are made of brass, therefore will not rust or be easily broken.

Having no parts exposed that can be injured, it can be used in any public street or yard, and cannot be manipulated without the aid of a key, which can be kept at a convenient place.

This Indicator Post can be supplied separate, and can be used on any other make of valve.

In ordering, fill in dimensions as indicated by arrows at letters A, B, E, or SEND A VALVE, WHICH IS PREFERABLE.

Always state number of turns to open Valve, and whether valve opens by turning to the LEFT or RIGHT.

NASON'S EJECTORS OR SYPHON PUMPS FOR RAISING WATER AND CONVEYING LIQUIDS.

Size Nos.-----	1	2
Size of Steam Connections	$\frac{3}{4}$ in.	1 in.
" Suction -----	$1\frac{1}{4}$ "	$1\frac{1}{2}$ "
" Discharge -----	1 "	$1\frac{1}{4}$ "
Price, Iron -----	\$3.00	\$5.00
" Brass -----	3.00	5.00

Like all Ejectors they are better adapted to service where the volume of water to be lifted is large, against a small elevation. For such service, and where the water is cold, they will be found to be fairly economical, and have the advantage over pumps for similar service, in having no valves or cramped passages likely to be obstructed or clogged by mud, gravel or other material likely to clog a pump.

The best results are given where the lift is low—not exceeding 15 to 20 feet, unless the steam pressure is very high, say above 70 lbs. The water may be lifted by them to a much greater height, but at the sacrifice of economy.

Among the numerous classes of work to which they are applicable may be mentioned that of raising water and other fluids from Tanks, Wells, Mines, Quarries, Holds of Vessels, Docks, Gas Works, etc.

NOTE.—Where economy in the use of steam is important these Ejectors are not recommended to lift over a height of fifteen feet.

THE HANCOCK "EJECTOR" OR JET PUMP.

Size.	Capacity Per Hour.	Pipe Connections.		Price.

" 8 "	8,800 "	$1\frac{1}{2}$ "	3 "	55 00
" 9 "	15,600 "	2 "	4 "	70 00
" 10 "	24,300 "	$2\frac{1}{2}$ "	5 "	110 00
" 11 "	35,000 "	$2\frac{1}{2}$ "	6 "	160 00

Sizes 1, 2, 3 and 4 are made entirely of brass.

Sizes 5, 6 and 7 have iron bodies and brass unions for steam and suction.

Sizes 8, 9, 10 and 11 have iron bodies with brass unions for steam only.

Sizes 5, 6, 7, 8, 9, 10 and 11 made entirely of brass—larger sizes, and Ejectors for handling corrosive liquids furnished on special order.

The "Hancock" Ejector is designed for use at Railroad Water Stations, on construction trains, for emptying wheel-pits and similar railroad service; also for transporting liquids, either hot or cold, in tanneries, dye houses, etc.

It is simple in construction, compact in form, convenient to handle, has *no movable parts*, and cannot get out of order, and is far more economical in the use of steam than any other similar apparatus.

All sizes will lift water 25 feet and elevate it about 15 feet above the Ejector with a steam pressure of 60 lbs.

If it is desired to elevate liquids a greater distance than 40 feet, the Ejector should be placed near the liquid so that it can be forced by the Ejector. In this manner liquids can be lifted about 50 feet with 75 pounds pressure and about 70 feet with 100 pounds pressure.

There must be *no leak* in the suction connections.

Before operating the Ejector blow out the steam pipe thoroughly to remove any iron chips, red lead, etc.

To use an Ejector economically regulate the steam with the Starting Valve.

The Hancock "Ejector" is furnished to operate with either steam, air or water.

Please specify on orders the steam, air or water pressure and service required.

CELLAR DRAINERS.

“CLIMAX”

The capacity of a Drainer depends upon amount of water pressure obtainable and lift, and it is advisable to have this information, with conditions under which Drainer is expected to work.

Sizes.	Pressure, Lbs.	Lift. Ft.	Capacity per hour. Gallons.	Pressure, Lbs.	Lift. Ft.	Capacity per hour. Gallons.
1.....	15 to 20	6 to 7	50 to 75	40 to 50	8 to 12	200 to 250
2.....	15 to 20	6 to 7	100 to 125	40 to 50	8 to 12	350 to 400
3.....	15 to 20	6 to 7	150 to 200	40 to 50	8 to 12	550 to 600
4.....	15 to 20	6 to 7	200 to 275	40 to 50	8 to 12	750 to 800
5.....	15 to 20	6 to 7	275 to 350	40 to 50	8 to 12	850 to 1000
6.....	15 to 20	6 to 7	350 to 450	40 to 50	8 to 12	1100 to 1300

These Cellar Drainers are made for draining cellars, wheel pits, furnace pits, etc., at the least possible expense and in a permanent and positively satisfactory manner. They are also desirable and largely used for removing waste water from kitchens below level of sewer and removing drippings from ice boxes, and for any purpose where it is necessary to remove water economically from one level to a higher one.

THE WORTHINGTON WATER METER.

The parts of the Worthington Meter have been made the subject of careful study, with the result that, as now furnished, the arrangement of counter movement and cap gear will be found a great improvement over that previously used, and it is believed to be superior to any arrangement employed for a similar purpose.

The framework and gear wheels of the counter movement are constructed of the best brass composition, the wheels themselves being accurately cut by means of special machinery, and all the pinions are constructed of German silver, these also being cut with special tools.

The counter is covered with a cast iron box, the lid of which, being raised, the dial can be seen through the glass in the top of the box; this box is screwed to the body of the meter; and by covering the heads of the screws with sealing wax, stamped with the seal of the water works corporation, it becomes impossible to tamper with the counter movement without breaking the seal.

Should the ratchet movement that drives the counter become in any way deranged in transportation or otherwise, it can be reached by simply removing the counter box, without the necessity of the joints of the meter being disturbed or the water turned off.

TO PUT UP AND START THE METER.—Connect the supply pipe with the meter at the hole marked "Inlet"; the outlet pipe is on a line with the inlet pipe, on the opposite side of the meter; turn on the water and loosen the brass Vent Screws on the top of the meter, and allow the air to blow through. When water appears at the Vent Screws, tighten them again, and leave the meter to itself, noting the reading of the counter.

SIZES AND CAPACITIES OF METERS.

Size of Opening.	Greatest Proper Quantity Per Minute.	Price.	Permanent Box.*	Brass Couplings for connecting the Meters.	Strainers.
$\frac{5}{8}$ inch pipe	1 $\frac{1}{2}$ Cubic Foot, or 11 $\frac{1}{2}$ Gallons	\$19.00	\$1.00	\$0.95	\$3.50
"	3 " " " 22 $\frac{1}{2}$ "	28.00	1.50	1.10	3.50

4 " "	60 " " " 450 " "	375.00	----	3.00	25.00
6 " "	120 " " " 900 " "	900.00	----	5.00	----

Screw Flanges.

*This box has a hinged lid and is made very strong to protect the meter in transportation and while in use. It has suitable openings for the pipe connections. Ordinary rough boxing charged at cost.

The quantities given in the second column of the above table represent a rate of delivery that can be considerably exceeded with this machine, but which had better be accepted as the maximum at which it is advisable to run any water meter continuously. Whenever in the effort to make a small machine answer for a large one, this rate is exceeded and greatly increased wear and tear are invariably the consequence.

CROWN WATER METER.

"A" STYLE.

THE CROWN METER is so well known and its popularity so universal that it does not require an introduction. At the present time it is in use in over 2,500 CITIES AND TOWNS in the United States, the Dominion of Canada and many foreign countries, and it has received the unqualified approval and recommendation of hundreds of our ablest Engineers and Water Works Officials.

The Crown, being positive in its action, will measure with absolute correctness all streams, whether large or small, under all the conditions of fluctuating pressures. Its accuracy has been proved by innumerable tests.

There are four main parts to the Crown Meter: 1st. The Cover, which includes the intermediate gearing, and the counter or registering mechanism. 2d. The Base, which contains the inside cylinder. The Base has the inlet and outlet spuds attached, and is arranged to be bolted to the Cover. 3d. Inside Cylinder. This consists of three parts: the Ring, and the top and bottom Cylinder Heads. The perfection of this Cylinder assists in developing the accuracy of the registration, as this is the part in which the piston revolves. 4th. The Piston. This is practically the ONLY working part. It is made of hard rubber, of about the specific gravity of water. The Piston has no bearing whatever, as it practically floats. It is perfectly balanced, and therefore FRICTIONLESS IN ITS OPERATION.

The entire meter—excepting the Cover and the Piston—is made of composition, consisting of a combination of metals unsurpassed for durability and wear, insuring the greatest possible resistance to corrosion. All Pinions, Spindles, Bearings or parts which have extraordinary wear are made of German Silver.

6	120 " 900 "	625.00		$36\frac{3}{4}$	$28\frac{1}{2}$	29	965

SPECIAL NOTE.—The prices mentioned above are the same for meters fitted with the round porcelain dials or for those arranged with the straight-reading registers. The meters arranged with the round dials are known as the "A" Crown, whereas those fitted with the straight-reading registers are classified as "AA" Crown. The "AA" Crown meters are made only in the sizes from the $\frac{3}{8}$ -inch to the 2-inch inclusive, whereas the Crown meters with the round dials are made in all sizes from the $\frac{3}{8}$ -inch to the 6-inch inclusive. Unless we are advised to the contrary, we always send the "AA" Crown meters in sizes from $\frac{3}{8}$ -inch to 2-inch.

NASH WATER METER.

ROUND DIALS. All sizes of the Nash Meter arranged with the round dials will hereafter be known as the "A" Nash. The counter or registering mechanism of the "A" Nash Meter is the same style and construction which have long been used with remarkable success on the Crown Meters. There are now in service thousands of Nash Meters fitted with the round dials, and which have been in continual operation for many years.

"AA" NASH METERS.

STRAIGHT-READING REGISTERS. Nash Meters arranged with Straight-Reading Registers are classified as "AA" Nash. Thousands of "AA" Nash Meters are in use in different sections of the country, and it is evident that the Straight-Reading Register is steadily growing more popular, as the demand for it is constantly increasing. The Straight-Reading Register is so simple that every consumer will be able to read his own meter without previous instruction.

NASON'S "GRIFFIN" FOOT RAIL BRACKET,

WITH CORNER AND END PIECES.

PATENTED 1882.

Foot-rail Bracket.—Large scale, showing design.

Corner Fitting.—Showing detail of design.

End Piece.

Acorn End Piece.

Rosette, for Railing.

NASON'S "GRIFFIN" FOOT RAIL BRACKETS.—Cont. CORNER AND END PIECES.

THESE BRACKETS ARE ARRANGED FOR ONE-INCH PIPE.

Foot Rail Bracket, shown as put up ready for use.

It has been our aim in designing the "Griffin Foot Rail Bracket," as illustrated herewith, to produce an article artistic in design, and fitted in form so as to bear the heaviest strain with the least possible chance of disarrangement, while at the same time a model of lightness.

It is almost impossible to fasten the foot rail to the bar itself and render it thoroughly secure and permanent; but with the "Griffin" bracket this object is secured, as the support comes from the floor, and is directly under the line of the heaviest strain, whereas, in the other case the foot-rest itself acts as a lever to loosen its own support.

Their design is artistic, and their lightness and beauty of form is such that they add to, and improve the appearance of, the most handsomely fitted-up surroundings; while in point of cleanliness they far surpass the gaping "Y" support now so commonly used, as they present no interstices where dirt of any kind can gather.

It may be mentioned that where rails with the old form of bracket are in use, the latter can be removed and substituted with the "Griffin" pattern without discarding the rail, and considerable expense be thus saved, while the handsome effect of a new rail will be given. We manufacture them in plain or galvanized iron, bronze and brass, and will furnish them at the following prices, net:

	Plain Iron.	Bronzed Iron.	Galvanized Iron	Artistic Brass.
Brackets.....	.50	.85	.85	3.50.
Corner Fittings.....	.50	.75	.75	3.00
End Finish Fittings.....	.15	.25	.25	1.40
Acorn End Pieces.....	.10	.18	.18	.65
Rosette for Railing.....	.08	.15	.15	.50

Or we will furnish estimate for fitting them up with the necessary rail, complete, in the very best manner.

These Brackets and Fittings are only made for One Inch Pipe.

NASON'S STEAM HEATER.

FOR GLUE, PASTE, ETC.

As shown above, the heater consists of a cast-iron box with cover, in which there are holes of suitable size to receive such pots as may be desired.

The heating surface consists of horizontal tubes screwed into a header, each of which has a smaller tube within it through which the steam enters, and a positive circulation—even under low pressure—is insured.

Exhaust steam being frequently used for heating purposes, the tubular form of the heating surface gives abundant heating area, and its efficiency is so greatly increased thereby that as good results are reached as if high pressure steam were connected to the heater.

Three sizes are made, numbered 1, 2 and 3, and below will be found a list of the regular sizes and number of pots which are commonly made for each heater.

Extra pots of the several sizes and materials are kept in stock and can be furnished as wanted.

Numbers.....	1	2	3
Sizes of Covers, inches	11 x 15½	16 x 22½	16 x 28¾
Depth, inches.....	7	9	9
Sizes and Numbers of Pots fitted up for each size	Two 5 in. only, or, One 8 in. only, or, One 9 in.	Six 5 in. only, or, One 10 in. and Two 5 in.	Two 12 in. only, or, One 12 in. and Four 5 in. or, Eight 5 in.
Price, without pots.....	8.00	16.00	20.00

COPPER POTS FOR GLUE HEATERS.

Diameter, inches.....	5	6	7	8	9	10	12
Depth, inches.....	5	5⅞	7¼	7½	7½	8	8
Price.....	2.00	2.25	2.50	3.50	4.00	4.50	5.50

Galvanized Cast-Iron Pots, 5 inch, 75 cents each.

We can furnish a number of additional sizes of covers for above Heaters.

NASON'S "IMMERSED-VALVE" BOILER FEEDER.

As hitherto made, all Automatic Water Feeders for boilers have been so constructed that the valve which governs the amount of water requisite for the boiler has been placed at the top of the Feeder, where the rubber seat is constantly exposed to the destructive action of steam, which is at or above a temperature of 212°

This rapidly destroys the gummy nature of the rubber in the valve, leaving behind it a hard residuum which speedily crumbles and it has therefore at frequent intervals to be renewed.

The difficulty has now been avoided by inverting the valve, its position being beneath the water, where as it is always kept wet and at a lower temperature, its durability is thereby greatly increased.

In making this alteration all the former valuable features of our Feeder have been retained, and while the alteration has added to their cost of manufacture their price has not been increased.

Among its most important advantages are the following:

All the copper floats used in them are made "extra strong" and carefully tested under pressure, in order to avoid to the greatest possible extent a danger common to all of them, that of collapsing,

The lever connecting the float with the valve is made as long as the form of the casing permits, a quarter turn in it between the valve and fulcrum enabling all interior space to be fully utilized.

Easy access is had to the valve with the least possible trouble by removal of the brass cap immediately below it; and the large opening facilitates its replacement with a new one, if injured or worn out.

All the valves are packed with Jenkins' packing, secured in a containing cup to give them the greatest possible endurance.

It is not advised that these Regulations be attached to boilers where the pressure exceeds twenty pounds, although as a matter of precaution, they are carefully tested to fifty before leaving the factory.

They may be used with or without a gauge glass, to be placed upon either side—holes being tapped for this purpose.

Outlets for the glass gauge are made on both sides of the Feeder in order that it may be connected in either side of the boiler as most convenient.

DIRECTIONS FOR USING.

Place the regulator near the boiler at such a height that its centre coincides with the line at which it is desired to maintain the water level in the boiler.

Connect the top opening on the large end of the receiver with the steam dome of the boiler above the water line, and the bottom opening with the boiler at some point below the water level.

The Feed Water connection is then to be made with the small end of the Feeder—care being taken in all cases to ascertain that the pressure in the water supply exceeds the greatest amount of pressure which the boiler is ever to be used under.

For the benefit or purchasers, the following dimensions are given, which may be of assistance in connecting the Feeder.

Outside Length.....	23 1/4 inches.
Height.....	13 3/8 "
Width.....	9 "
Size of Boiler Connection.....	1 "
Size of Gauge Glass Connection.....	1 1/2 "
Size of Feed Water Inlet.....	1 1/2 "
Price without Water Gauge.....	\$20.00
With Water Gauge, complete.....	24.00

IMPORTANT.

Note change in prices taking effect this date, 1st January, 1898.

VALVES, FITTINGS, GAUGES, ETC.**FOR ANHYDROUS AND AQUA AMMONIA—ADAPTED TO AMMONIA MACHINERY FOR ICEMAKING AND REFRIGERATING PURPOSES.**

The revised and enlarged price list herewith submitted for our Ammonia specialties supersedes all earlier lists. As in the past, a special alloy of cast iron and steel will be used in these castings and the same exacting test of 500 to 1,000 lbs. pressure placed upon them. The same care will also be given to the cutting of threads, so that our patrons may be assured of the absolute reliability of the joints and the perfect integrity of the fittings. The great popularity of our ammonia fittings renders exhaustive description unnecessary, yet we wish again to invite attention to the "NASON" Joint, originated by us, and which we are always willing to guarantee under all usual conditions of ammonia service. The construction of the joint is as follows:

FIG. 1.

The ends of the pipes to be connected being first threaded as for an ordinary fitting, they are then screwed into the fitting securely, and the addition of a stuffing-box with gland and rubber washer above the thread (as shown in Fig. 1) perfectly closes the joint when tightened down, rendering leakage impossible.

Owing to the largely increased use of artificial refrigeration during the past few years, and the great strides made toward the perfection of this class of apparatus, we have found it necessary from time to time to make additions to our patterns for Ammonia Specialties, in order to meet the increasing demand and varied requirements of the different machines placed on the market; so that our list as now submitted will be found full and complete, covering all fittings generally used in ammonia apparatus, whether of large or small capacity, and of either the Compression or Absorption type.

Among the many good features which have tended to increase the popularity and demand for our ammonia fittings, their absolute reliability is not the least; and we wish to assure our patrons that the same care will be used in their manufacture as in the past and that the same dependence may be placed upon their perfect integrity.

An alloy of cast-iron and steel is used in making the castings; the threads are cut with every care and carefully examined; and on the completion of all fittings they are subjected to a rigid pressure of from five hundred to one thousand pounds—such as are found in any way imperfect being rejected.

We wish also to call attention to the increase in our list of sizes and patterns for special fittings for Brine Circulation—particularly in the group of Return Bends. As the circulation of cold brine as a cooling agent has become almost universally recognized as the safest and most effective method of reducing temperatures in cellars, beer vaults and cold storage buildings, we have found it necessary to increase our line of patterns and fittings for this service, with the view of placing on the market return bends and elbows having both greater distances between centres and longer curves to reduce friction in circulating brine through them.

The bends here shown are cast-iron, but our shops are fully equipped with special tools for turning out bends and elbows from wrought-iron pipe, either common or extra strong, bent to any practicable radius, and threaded as may be required. Prices for these are also given.

Attention is also called to the revised list of sizes as now published, covering our assortment of patterns for ammonia headers, to which we have recently made considerable additions, so that all reasonable requirements in this direction can now be met.

As will also be seen, we have now a complete line of Ammonia Check Valves up to and including three and a half inch.

Finding that the growing (and usually urgent) demand for our Ammonia work warranted us in so doing, we have introduced in our shops, for this particular branch, improved machinery specially designed, in order that all material sent out may be of first-class workmanship and thoroughly tested, and also with a view of always carrying a full line in stock, which we are confident will be appreciated by our customers and lead to a more extended introduction of these goods throughout the country.

We take especial pleasure in referring to many of the largest users of ammonia, and solicit correspondence, when fuller particulars will be given, if requested, and special rates named on specifications submitted.

NASON'S NEW STEAM AND HOT WATER HEATERS.

PATENTED OCTOBER 28TH, 1890.

With this edition of our catalogue, we take pleasure in presenting our improved "EQUATOR" (steam) and "GULF STREAM" (hot water) Heaters, showing our new design sectional shaking and dumping grate, and other minor features tending to perfect and further enhance their already well-known superior qualities.

THE "EQUATOR."

In planning this heater, the following features were borne in mind, and all the requirements will be found to have been met, on an examination of the heater and its method of construction.

The surface must be large as compared with the area of the grate.

It must be as far as possible all of it exposed to the direct rays of the fire.

The fire door must be large for convenience of firing.

The fire box must be deep and roomy in order to give a large combustion chamber, and also serve as a liberal receiver to contain coal over night.

The grate must be of the shaking pattern, and arranged to dump readily without opening the fire or ash pit doors.

The door for regulating air supply under the grate should be separate from the ash pit door in order that it shall be always clean, and also to avoid the annoyance of a chain on the heater front, where it is likely to interfere with the ready use of both fire and ash pit doors.

A proper mud drum should be provided, in which accumulations of dirt or scale will settle, from which they may be drawn at the convenience of the person in charge of the fire.

The heater must evaporate a large amount of water for each pound of coal burned in it, or for EACH DOLLAR SPENT FOR FUEL.

In construction the heater is of the drop tube type, the reservoir on top being constructed of cast iron, and the tubes of mild steel.

Into the bottom head or crown sheet—the latter being strengthened by suitable braces—are screwed a number of one inch drop tubes, excepting on the outer row, where for the purpose of stiffening the heater for shipment 1½ inch tubes are used. The lower ends of all these tubes are closed by our patent welding process, and into each is fitted a wrought iron diaphragm—their thickness being four Nos. heavier than that used for radiators.

This insures an active circulation in all of them—water passing down on one side and up the other, conveying the steam bubbles into the reservoir above, where it separates from the body of water.

The smoke and gases after passing over the tube surface are discharged through a central tube in the steam cylinder—a baffle plate compelling them to thoroughly circulate among all the tubes before they pass into the chimney.

In a heater of this type we have found it practicable to get as large a ratio of heating surface to grate surface as 40 to 1—this being at least 25 per cent. more than any other house steam heater now in the market.

Between each of the 1½ inch tubes, at their lower ends, is inserted a fire brick made expressly to fit their shape, which serve the purpose of keeping the exterior of the fire from coming directly in contact with the cooler surface of the pipes, which would hinder combustion and make the fire sluggish.

At the same time the pipes keep the fire bricks partially cooled so that they are not injured to the same extent as where a furnace is entirely lined with brick.

Attention is called to the casing—the inner surface of which is made of ¼ inch asbestos board, covered by heavy galvanized or Russia-iron; this being held in place by wrought iron bands clamped together at the back with bolts. In this construction, a neatness of appearance is attained which can be got in no other way; and if necessary at any time the casing can be removed and replaced in less than an hour.

The fire door is surrounded by a hollow cast-iron casting, which is connected to the steam reservoir above by two 1½ inch pipes, and through these all dirt in the heater gradually settles, all sediment being driven out of the smaller tubes by their activity of circulation, and the accumulation is drawn from the bottom of the casting through a cock left there for that purpose.

In a heater of this type it is obviously impossible to empty water from the tubes by drawing off, and, foreseeing the possible danger from freezing, we made a carefully conducted series of experiments to ascertain what the probability of accident from this cause would be.

We developed the fact that when water freezes in the tubes the ice, instead of exerting its expansive force transversely, is forced up into the drum of the heater without causing any injury to the tubes whatever.

Where it is thought best for any reason to expel the water from the tubes, it can be always done by building a light fire of shavings in the heater. But this we do not recommend except when done by a competent engineer, as there may be danger of causing leakage by overheating.

In ordinary practice there is no objection whatever to leaving the water in the tubes, and we are willing to guarantee all our heaters of this type against any damage whatever occurring from this cause, providing the water is drawn from the steam drum and fire-door casing.

Customers are invited to see samples in our office of heater tubes which have had water frozen in them.

The main body of water in the heater is drawn from the bottom of the mud drum, which operation also empties the latter at the same time.

Each heater is furnished with a complete set of Water Gauges, Gauge Cocks, Safety Valve, Automatic Damper for regulating the draft, Check Draft on top, and a complete set of fire tools.

Further information with prices furnished upon application.

DROP TUBE FIRE SURFACE.

Almost the entire fire surface of the heaters is made up of drop-tubes suspended directly into the fire-box. It is at once obvious that their position with relation to the fire is such that every square inch is directly exposed not only to the heated products of combustion, but to direct radiation of the heat from the fire itself. The lower ends being securely welded, their only joint is at the upper end where they are screwed into the tube sheet of the heater, at which point the temperature of the gases is so reduced that injury from burning is impossible. Almost all of this surface is exposed directly to the fire itself, so that the remarkable result in evaporating efficiency attained greatly exceeds that of any other house steam or hot water heaters made or sold.

CIRCULATION IN TUBES AND THEIR EVAPORATIVE DUTY.

By the construction above described, provision is made for the rapid vertical flow of water in each tube, independent of all others. When water is heated it becomes of lesser specific gravity, and as a consequence there is a tendency of the hot water to rise vertically, the cooler water descending on the other side of each diaphragm to take its place; and in passing through a heater, the circulation in any other direction necessarily retards it. Whenever the whole body of water in any heater flows in one long or devious circuit, as in the case of all flat disc or horizontal tube heaters, it of necessity moves slowly, and when the fire is strong, with more or less noisy ebullition; but the water in our heater flows in many independent short vertical circuits, and its movement is consequently very rapid, the distance traveled from the fire surface to the point of release being short; as a consequence steam passes rapidly to the steam-dome, ebullition is very quiet and the production of large bubbles on the heating surface is avoided. This rapid circulation also insures freedom from deposit at the bottom of the tubes, it having been demonstrated with a heater of a type like this that lead shot can be thrown out of the tubes by rapid circulation.

SELF CLEANING.

Not least among the many excellent features of vertical tubes is that no soot or dust can collect by gravity on the fire surfaces, while upon every flat portion of the tube, disc, or horizontal heaters, whether of the water-tube or fire-tube class, a large collection of detritus is inevitable. These heaters are thus entirely "*self cleaning*."

DIAPHRAGMS AND THEIR DURABILITY.

As the question may be asked as to the probable life of a diaphragm placed in a tube for the establishment of circulation, we promptly answer that it will be at least as long as that of the whole apparatus. No deterioration is observable in the diaphragms of vertical tube radiators, which have been in use for more than thirty years past, and where the conditions are less favorable than in a heater, the radiator sheet iron being thinner than that used for the drop-tube diaphragm.

Their destructibility is practically unknown. We have in many instances for purposes of examination into this point removed diaphragms from radiators which have been used for over twenty-five years, and found them practically as good as when first made, the original scale and marks on the surface of the iron being still intact. In the case of a heater, where the tubes are constantly immersed in water, the condition is much more favorable for the preservation of diaphragms than in radiators that are alternately subjected to contact with steam or air.

FIRE TILE LINING.

This feature, as here illustrated, is one of the most important in both the "GULF STREAM" and "EQUATOR" heaters.

SECTION OF FIRE-POT.

Each size of heater requires a separate pattern moulded so as to exactly fit the space between the tubes. They are kept in stock and can be shipped immediately on order by mail or telegraph.

The cut shows distinctly the mode of insertion. Each tile is notched on the top sufficiently to allow it to be raised enough to pass over the small lug which holds each in place at the base. No cement or setting is required; the weight of each brick and its form hold it positively in place, and their renewal is so simple a matter that it can be done by any housekeeper without calling in the services of a steam-fitter or machinist.

THE "GULF" STREAM HOT WATER HEATER.

This heater is similar in construction to the "Equator," except that the steam dome, instead of being of large size to allow the separation of steam from the water, is cut down in height, so as to merely serve the purpose of conducting the water to the tubes and away from them after it has been heated.

The same large proportion of surface to grate is maintained, and the heater is precisely similar in all respects, except that the flow and return connections, and the trimmings are different.

REMOVAL OF ASHES.

Too much emphasis cannot be placed on the necessity of keeping the ash-pit free from ashes, which are liable to accumulate through carelessness or laziness of servants.

The ashes should be regularly removed at least once a day and placed in an iron ash barrel.

If ashes are allowed to accumulate, the grate bars will inevitably be made red hot, which warps and destroys them in a short time.

A grate, with proper care, will last for several years, or on the other hand the best grate may be spoiled in a day or two by a careless disregard of the above directions.

Both the "GULF STREAM" and "EQUATOR HEATERS" require no attention whatever as to cleaning. Their construction is such that, unlike other heaters, they clean themselves, and the fire surface is always free from soot and dust, and much dirty work and loss of heat is thus avoided.

DIRECTIONS FOR SETTING UP.

1st. Place the bottom casting on the smooth cellar floor where it is to stand, as near the chimney as possible so as to avoid a long horizontal smoke pipe.

The floor should be smooth, and about the heater, covered with brick or stone when possible.

2d. Place the two half pieces which encircle the grate in position, care being taken that the opening left in the ring for the projection of the grate spindle comes opposite the hole in the front of the base-casting. Then place the grate in position, allowing the spindle to project through the front.

3d. Raise the heater, taking care to avoid bending the outside tubes, and place it upon the bottom casting. Where practicable this can be most easily done, for the larger sizes, by screwing an eye-bolt into the bottom of a timber, directly over the place where the heater is to stand and then hoist it into position.

4th. Place the loose pieces of fire-brick between the outside row of tubes inside the fire-box. It will be noticed that they are so shaped that, when placed in position, they will remain there of their own weight.

5th. Put the semi-circular pieces of iron outside the outer row of tubes and secure them in place with the bolts provided.

They are for the purpose of holding the asbestos covering in position, keeping it a slight distance from the pipes and thus allowing the ashes to sift in from the fire-box; as they make a good non-conducting lining in addition to the asbestos.

6th. Wrap the asbestos covering around the heater and tie with wire. Its position is clearly shown by the openings in it and by the marks in paint at the joints.

7th. Put the galvanized iron casing outside the asbestos and bolt up the wrought iron straps, giving tension enough to hold the whole securely.

8th. Put on the trimmings as shown in the accompanying cuts.

NOTE. In order to bring the galvanized iron casing into position before bolting on the girth straps, it may be found convenient to place a turn of wire once around the jacket, tightening it by twisting with a piece of steam pipe or stick, to draw the edges into place.

OUR "PERFECTED" GRATE.

A demand having arisen for a Grate to be used in association with our Equator and Gulf Stream Heaters, which would more perfectly control the fire and its management, we have devised a form which is distinctly new in many of its features ; and after a careful trial the Grate is now for the first time offered, and all our Heaters sent out in the future will be equipped with it.

An examination of the accompanying cuts will sufficiently show its construction and general operation. Fig. 1, is the Grate ready for use ; Fig. 2, the bars in position for dumping the fire, and Fig. 3, a section of the ash-pit and bars.

Fig. 1.

GRATE SET READY FOR USE.

It will be noticed that each bar is formed with two lateral stays running its whole length to the trunions, instead of one as is commonly used. Across the stays are ties with short pieces or fingers extending on both sides. This method of construction gives greater stability, with less weight, than with any other form, and also largely increases air space, ensuring both better combustion, and cooler bars, with their consequent longer life.

Fig. 2.

POSITION IN DUMPING.

Shaking the Grate is accomplished with a handle attached to the center bar spindle; motion to the left being arrested by the Grate striking the ring, and to the right by means of the pawl which catches in a notch in the spindle provided for it.

When it is desired to dump the entire contents of the fire box the pawl is thrown back to the left, leaving the spindle free to make a quarter turn to the right, and place the Grate bars in a nearly vertical position.

Fig. 3.

SECTION OF ASH-PIT AND GRATE.

The position of the Grate is somewhat higher than in the previous pattern, and the depth of the bars is also less, which feature gives considerably more height of ash-pit than formerly, and will be appreciated by those especially who are using the Nos. 4 and 5 sizes.

The outer circle ring of these Grates fits the base of all Heaters we have issued; and the outer bar section of all Grates we shall make are similar, but there is a slight difference in the construction of the central bars, there being two patterns, one for bases of the earlier form which had the Grate below the level of the ring, and the other for all new bases shipped after this date.

NOTE.—Customers in ordering Grates for Heaters, should invariably give the date at which the original Heater was sold, in order that the proper pattern may be sent.

Letters Patent have been applied for, and will shortly be issued, of which due notice will be given.

Each pipe measures one square foot of surface.

Square feet of heating surface in all these Radiators can be increased or diminished by varying the length of the tubes.

NASON'S VERTICAL WROUGHT IRON WELDED TUBE RADIATORS.

The Nason Radiators have been so long and so favorably known as to render any very full description of their construction unnecessary, but certain improvements which have been recently adopted in their form and manufacture will prove interesting to the trade.

While retaining the original pattern of base and top for use where a heavy and massive appearance is desired, the general demand for a radiator combining elegance of form with strength, induced us to undertake the large labor and expense of making an entire new set of patterns, which design has to-day nearly supplanted the previous form. This pattern we have named NASON'S IMPROVED, and radiators should be ordered under this name unless the old pattern is desired.

The most marked improvement is the form of the base, the latter being so constructed as to admit air through apertures between each of the pipes. These holes are circular, and made slightly conical in form, so that each is in fact a small blow-pipe which directs a current of cold air, taken from the floor, where it is coldest, directly upon the adjacent pipes, and this enormously increases their activity in heating the air. By this device the inner rows of pipes are rendered almost as active as those on the exterior, and less heating surface than has been commonly used in the past can be employed in a room of given size.

There will also be found a considerable number of intermediate sizes not found in earlier editions of our catalogue, which have been made in compliance with the often expressed wish of customers, to fill the gap between certain sizes—notably those between 48 and 60 pipes and 24 and 32.

Also, there are several new smaller sizes here presented for the first time, especially adapted to small rooms in apartment houses, so that the exact proportion of surface to volume can be given, instead of putting in an excess or deficiency of surface, as has often been found necessary.

There are also included two patterns specially made to condense a large amount of heating surface into a small space, where but little of the latter is available and the floor area restricted.

By means of our recently patented welding process for closing the tops of tubes, a uniformity in their length and appearance is secured which is highly desirable; also absolute freedom from leakage is obtained. The process being done by machinery, all welds are subjected to precisely the same pressure.

All radiators are tested under a pressure of 70 pounds boiler pressure, insuring to a certainty that no leaks will occur when less than this is used. If a higher pressure is to be used it should be specifically so stated in the order, so that such radiators may be specially tested and the requirements met.

Each pipe measures one square foot of surface.

Square feet of heating surface in all these Radiators can be increased or diminished by varying the length of the tubes.

All tubes in our radiators being cut to a standard thread, they may be readily removed from a base, when the latter is connected in the building, without breaking its connection, if it is desired at any time to increase or diminish the heating surface by lengthening or shortening the tubes.

This feature is possessed by none of the return bend pattern.

As manufactured in our radiators the form of material is less than half the thickness of the cast iron loops or tubes commonly used, and it is apparent to any one that the thinner the material, or, in other words, the closer the air can be brought within direct contact of the interior steam heated surface of a radiator, the more rapidly the heat will be transmitted from the steam to the air.

It is well known, too, that sand is an excellent non-conductor—it being frequently used for insulating purposes, and the impossibility of properly cleaning the interior of cast iron radiators from sand which is left by the cores and burned into the casting, makes this coating on the inside a serious obstructor of heat passing through it.

Attention is respectfully called to the carefully made series of experiments recently conducted by the well-known engineer and expert, Mr. George M. Barrus, of Boston, for the purpose of ascertaining the relative heating efficiency of our Improved Radiator as compared with cast-iron surface, an abstract of which will be found on pages 161-161½

The extraordinary efficiency shown by Mr. Barrus's experiments is due in a large measure to the fact that the radiating surface is composed chiefly of wrought iron instead of cast.

THEORY OF CIRCULATION.

Although the question of the active circulation of steam in the Nason Tube was settled years since, both by theory and results in practice, derived from the millions of square feet of surface sold by us, it is occasionally raised by parties not familiar with, or who have been misled by interested competitors, and for their benefit cuts Nos. 1 and 2 are here included.

NO. 1.

NO. 2.

No. 1 shows horizontal section of a standard tube, with the form of diaphragm and its method of insertion. It will be observed that it fits the tube closely, thus dividing

Each pipe measures one square foot of surface.

Square feet of heating surface in all these Radiators can be increased or diminished by varying the length of the tubes.

the latter into two parts as efficiently as if there were two tubes connected at the top by means of a return bend.

In cut No. 2 it will be noticed that the diaphragm is driven nearly to the end of the tube—a space however being left sufficient to permit of the easy passage of air or steam over it.

The theory of circulation is as follows:

One hundred cubic feet of air at 60 degrees weigh 7.6 lbs. One hundred cubic feet of steam at 212 degrees weigh 3.6 lbs., from which it is evident that steam is nearly 53 per cent. lighter than air.

Each tube when screwed into a base thus stands in the relation of an inverted siphon to it, and on the admission of steam into the latter, it is obvious that air being so much the heavier, it will immediately drop down on one side of a diaphragm—no matter which—and its place occupied by steam which rises on the opposite side, thus following the air and supplanting it.

The heavier air falling in the base is immediately ejected through the return pipe, so that an interval of a few seconds thus suffices to entirely fill the radiator with steam

DURABILITY OF DIAPHRAGMS.

It may be of interest to customers who have been informed that the diaphragms inserted by us are perishable and will rust out after a few years' use, to know that some of the first radiators which we made, about twenty-five years since, were placed in the Fifth Avenue Hotel of this city; and after a continuous use for the above period, we recently, by the kind permission of the proprietors, Messrs. Hitchcock & Darling, removed several of the diaphragms, which are now in our office and open for inspection, together with many others of about equal age, which are equally as perfect. The original scale of metal on them has been little attacked; and the diaphragms of this age are usually quite as good as the many samples we have.

Steam in itself is a perfect protector of iron, and the vertical position in which the diaphragms are placed drains from them immediately all water which is deposited on them.

Upon the entrance of air, from leakage or otherwise, after the steam is turned off, there is no water present to rust the surface.

These facts are borne out by the many samples in our possession.

In an experience covering twenty-nine years (Radiators with Diaphragms inserted in the tubes having been made by us in 1860), we have never learned of an instance in which diaphragms have rusted out, or tubes to be refitted with them in consequence of their destruction.

Each pipe measures one square foot of surface.

Square feet of heating surface in all these Radiators, can be increased or diminished by varying the length of the tubes.

From the large number of sizes made, a few illustrations only are selected, which serve sufficiently to show their general style and appearance.

The following show our Nason Improved Pattern as made in four different widths.

Single Row Radiator.

Two Row Radiator.

Three Row Radiator.

Four Row Radiator.

In ordering specify "Improved" Pattern.

Each pipe measures one square foot of surface.

Square feet of heating surface in all these Radiators can be increased or diminished by varying the length of the tubes.

The annexed price-lists include only what are known as regular sizes, which are usually kept on hand, or if not on hand, can be promptly furnished. The prices include open-work Iron Tops. Binders for marble tops will be furnished when ordered, but as the use of the latter is attended with considerable loss of efficiency, they are not recommended except in special cases.

NASON'S "IMPROVED" VERTICAL TUBE RADIATORS.

PATTERN NO. 1. SINGLE ROW OF TUBES. Outside width at floor, $5\frac{1}{2}$ in.; usual height, 35 in.

PLEASE NOTE change in size of Radiator Connections, which are different from those previously issued by us. When desired they can be tapped to any required size or with extra large openings on the returns where they are to be connected to an apparatus constructed on the one-pipe system.

Cut showing both outlets on one end.

When necessary they are furnished as above shown with both steam and return on the same end. A positive circulation being established in this way through the base by means of a vertical diaphragm cast in the latter.

This form of construction facilitates connection to the risers and returns of an apparatus, and reduces its expense, as the main pipes are commonly placed side by side in large buildings.

When inlet and outlet are both on one end, their distances apart from centre to centre are for 2 pipes wide pattern 3 in.; 3 pipes wide pattern 4 in.; 4 pipes wide pattern 4 in.

Both holes are at the same height above the floor, or $3\frac{3}{4}$ in.

NO. 3.

Each pipe measures one square foot of surface.

Square feet of heating surface in all these Radiators can be increased or diminished by varying the length of the tubes.

For the benefit of steam fitters cuts Nos. 3, 4 and 5 are here introduced, to enable them to lay out connections to the mains ready to receive the radiators. Scale is one-quarter full size, and figures indicate distances from floor to centre of inlet pipes.

Where both openings are placed at one end of a base the distances are the same as above given.

Openings for either inlets or outlets can be made of varying sizes when so ordered, to suit the requirements of the trade, without extra charge.

NOTE.—All dimensions given are for return ends, inlets being $\frac{1}{4}$ inch higher.

Each pipe measures one square foot of surface.

Square feet of heating surface in all these Radiators can be increased or diminished by varying the length of the tubes.

No. 6.

Cut No. 8 represents our latest pattern of Box Base to be used for the Direct-Indirect System now becoming deservedly popular. It is in use in many well-known public buildings, notably in a number of the public schools in this city, where large numbers are in operation.

No. 7 is the same radiator provided with an air inlet on the base for admitting air directly from the room when for any reason, as, for instance, it is desired to heat a room quickly, the outside supply is shut off, and immediately transforms the radiator into the regular pattern.

This pattern is furnished with an outlet in the back of the base casting, which will be made of any dimensions desired, or air may be taken in at the bottom through the floor.

This form of base affords the best possible method of admitting air to rooms on the direct-indirect system, which is becoming deservedly popular, as owing to the large number of openings equally distributed in the base, no air can enter without coming immediately in contact with every part of the heating surface, thus becoming at once and thoroughly warmed. Each tube thus does its full share of work, and contributes greatly to the heating efficiency of the radiator.

The dimensions, &c., are identical with those of our new pattern as described on page 6 except that the distances from center of the outlets to the floor are: Inlets, $4\frac{1}{8}$ inches; outlets, $4\frac{7}{8}$ inches.

Each pipe measures one square foot of surface.

Square feet of heating surface in all these Radiators can be increased or diminished by varying the length of the tubes.

No. 7

LIST OF STANDARD SIZES AND PRICES OF
DIRECT-INDIRECT OR BOX BASE RADIATORS.

In ordering please state explicitly whether Bases are to have doors on the front, openings on the back or both.

Price for Door fitted to each Base, \$1.75.

Each pipe measures one square foot of space.

Square feet of heating surface in all these Radiators can be increased or diminished by varying the length of the tubes.

BOX BASE RADIATORS.—*Continued.*

The openings into which Doors can be fitted in front side of Box Base Radiators are $6 \times 3\frac{3}{4}$, $8 \times 3\frac{3}{4}$, $10 \times 3\frac{3}{4}$ inches.

The following measurements are the dimensions of the openings in the back side of Box Base Radiators.

2x4 $3\frac{1}{2} \times 6$	2x6 $3\frac{1}{2} \times 8$	2x8 $3\frac{1}{2} \times 8$	2x10 $3\frac{1}{2} \times 8$	2x12 $3\frac{1}{2} \times 8$	2x14 $3\frac{1}{2} \times 8$	2x16 $3\frac{1}{2} \times 8$	2x20 $3\frac{1}{2} \times 8$	2x24 $3\frac{1}{2} \times 8$
2x28 $3\frac{1}{2} \times 8$	3x4 $3\frac{1}{2} \times 6$	3x6 $3\frac{1}{2} \times 8$	3x8 $3\frac{1}{2} \times 8$	3x10 $3\frac{1}{2} \times 8$	3x12 $3\frac{1}{2} \times 8$	3x14 $3\frac{1}{2} \times 8$	3x16 $3\frac{1}{2} \times 8$	3x18 $3\frac{1}{2} \times 8$
3x20 $3\frac{1}{2} \times 8$	3x24 $3\frac{1}{2} \times 8$	3x28 $3\frac{1}{2} \times 12$	4x4 $3\frac{1}{2} \times 6$	4x8 $3\frac{1}{2} \times 8$	4x10 $3\frac{1}{2} \times 8$	4x12 $3\frac{1}{2} \times 8$	4x16 $3\frac{1}{2} \times 8$	4x20 $3\frac{1}{2} \times 12$
			4x24 $3\frac{1}{2} \times 12$	4x28 $3\frac{1}{2} \times 16$	4x32 $3\frac{1}{2} \times 16$			

Unless otherwise ordered, our box bases will be sent without opening either in the front or back—the air supply being commonly through an opening in the floor, as this method of connection avoids the necessity of making a joint with a tin air box at the back.

When doors at the front are wanted it should be specifically stated.

Dampers controlling the air supply are not furnished, owing to the varying methods in which air is introduced, and the forms of air inlets from the flues to be adopted.

They may be of the swinging type, like an ordinary stove damper, or when more convenient, of a sliding grate pattern.

Up to and including sizes 16 tubes in length, the boxes are cast with the bases in one piece. The longer patterns have cast iron boxes fitted on to which the base casting is readily set and attached with screws.

THE DIRECT-INDIRECT SYSTEM.

The good results predicted for this method of heating during the last few seasons have been so entirely satisfactory as to more than come up to our anticipations.

By this method, as is generally understood, the space beneath the base of radiators is enclosed, and air from the exterior supplied to it by means of air boxes in the cellar, or in some cases directly through the wall from the outside. Air then passes up through holes in the base and between the pipes, where it is thoroughly warmed before entering the room.

Our particular form of radiator is the most perfect which has yet been devised for this method of heating, because of the numerous inlets through which the air passes, thus sub-dividing it and bringing the current against every portion of the inside rows, as well as the exterior tubes.

The form of the orifices being circular, each acts as a small blow-pipe directly against the tubes, thereby greatly increasing their steam condensing effect, which necessarily means that correspondingly large volumes of air are warmed.

By this system the whole surface of the radiator is actively in operation, instead of the inside pipes being, as is common with most radiators, immersed in a warm air bath, where they are comparatively inoperative. Thus, owing to the great activity of the surface a considerably lesser number of square feet of surface can be placed in each room with a certainty of warming it than is ordinarily used.

In very cold or windy weather, when it is not desirable to take air from the exterior, the outside damper is then closed, and the door in the front of the base, by being opened, immediately places the radiator under the same conditions that a radiator of the standard type is working under.

These conditions are : That the cold air from the floor enters the door in the base, passes through the air openings over the tubes, and it is then distributed throughout the room.

This system is to be commended as possessing at once all the advantages of both systems, having the desirable quality of giving radiant heat in a room, besides warming air with which the surface comes in contact, and also giving more or less ventilation, the latter being controlled directly in rooms where it is wanted as readily as where registers are used.

*Each pipe measures one square foot of surface.
 Square feet of heating surface in all these Radiators can be increased or diminished
 by varying the length of the tubes.*

NO. 8.

No. 8 illustrates a convenient method of connecting our box base pattern with the indirect cold air flue. It will be noticed that air can be taken from the exterior of the building or entirely cut off and air circulation established from the room by opening the door in front of the base,

Air may be admitted either at the side of a building or through a flue running to a cellar; but it is not desirable to take air in through a vertical flue running to any point above the radiator, as an inverted current may be established on a windy day where radiators are run on the leeward side of the building, and the heated air be thus drawn from the room.

THE NASON HOT CLOSET OR DINING-ROOM RADIATOR.

Special attention is invited to our new DINING-ROOM HOT CLOSET RADIATOR, of which we have now on hand a full stock of different sizes, ready for immediate delivery.

This form of heater is placed on the market with a view to meeting the constant and increasing demand for a Dining-Room Radiator that, while handsome in appearance, will be reasonable in price.

As shown in the accompanying cut, it will be seen that it has the advantage over several other patterns now offered by being enclosed on three sides by heating surface. Each closet is furnished with three perforated shelves which are readily adjusted to any height desired by means of side racks cast for this purpose.

For this Radiator the patterns have been made with great care from Bronze, for the purpose of obtaining castings as smooth and perfect as possible. The general appearance of the heater, as will be seen from the cut, is neat and ornamental, and when finished in Gold or Silver Bronze it becomes a handsome piece of furniture in any room.

The projection of the doors in front allows the introduction of dishes to be warmed of a width up to $13\frac{1}{2}$ inches. Patterns permit the extension of the length of the Radiator irrespective of the size of the closet, in order to adapt its heating surface to the dimensions of the room in which it may be placed.

This Radiator is made only in our four-row-wide pattern, and the internal dimensions of the closet in any pattern are: $13\frac{1}{2}$ inches in width, by 19 inches long, by 29 inches in height.

On application a Photograph will be sent by mail.

Following we give the list of sizes in which the Hot Closets are made, with list prices, and the square feet of heating surface in each.

Pattern.....	4x16	4x20	4x24	4x28	4x32
Heating surface in square ft.....	30	46	62	78	94
List Prices, Plain.....	\$33.00	\$40.00	\$47.00	\$54.00	\$61.00
Bronzed, in Gold or Silver.....	38.50	47.00	55.50	64.00	71.00

*Each pipe measures one square foot of surface.
 Square feet of heating surface in all these Radiators can be increased or diminished
 by varying the length of the tubes.*

Single Row Radiator.

Three Row Radiator.

Two Row Radiator.

Four Row Radiator.

This pattern is for Low Pressure to 40 lbs.
 In ordering specify "Solid Base" Pattern.

Each pipe measures one square foot of surface.

Square feet of heating surface in all these Radiators can be increased or diminished by varying the length of the tubes.

NASON'S "SOLID BASE" PATTERN VERTICAL WROUGHT IRON WELDED TUBE RADIATORS.

These are similar in construction to the new pattern described on the previous pages, except that they are heavier and more substantial in appearance, also more elaborate in design.

In handsomely furnished dwelling houses they are frequently used where a radiator of extra finish is desired.

As in the case of the new pattern, each tube is guaranteed to equal one square foot of surface.

PATTERN NO. 1, SINGLE ROW OF TUBES		Outside width, $4\frac{1}{2}$ inches ; usual height, 3 feet.							
Sizes of steam openings—Inlets, $\frac{3}{4}$ inch.		Outlets, 1 inch.

Price, plain.....	10.50	18.25	27.00	34.50	43.00	50.50	57.50	65.00	
Price, bronzed.....	12.00	21.00	31.00	40.00	50.00	58.00	65.00	74.00	

The inlets and outlets, if not wanted as above named, will be made as desired.

It will be noticed that the Outlets to Radiators in the foregoing tables are larger than the Inlets. They are made thus because when intended for single pipe connection the Outlets, being the lower, they can be tapped larger for the purpose of admitting steam and taking the water of condensation through the same pipe. *When otherwise intended, both Inlets and Outlets will be tapped as ordered.*

These Radiators are considerably more efficient than those made of cast iron. This must be so, since *wrought iron is the best surface in use for steam warming radiation.*

NASON'S "STANDARD" PATTERN.

VERTICAL WROUGHT IRON WELDED TUBE RADIATORS.

CIRCULAR PATTERN.

USUAL HEIGHT, ABOUT THREE FEET.

Pattern Number.	No. of Tubes.	Sq. Feet of Radiating Surface.	Outside Diameter at Floor.	Centres of Holes above Floor.		Inlets. Inches.	Outlets. Inches.	Price for Plain.	Price for Bronzed.
				Inlets.	Outlets.				
1	18	18	13½	3¼	2½	¾	1¼	11.00	12.25
2	30	30	18	3¼	2½	¾	1¼	17.00	19.00
3	54	54	23	3¼	2½	¾	1¼	28.50	32.00
4	72	72	25¾	3	2½	1	1¼	35.50	40.50
5	102	102	34	4½	4	1	1¼	54.50	62.00
6	130	130	38¼	4½	4	1¼	1¼	67.00	76.00
7	160	160	38¼	4½	4	1¼	1¼	80.00	91.00

The heating capacity and the cost of Circular Radiators may be varied by leaving out any number of Tubes, except the outer row, without changing the external appearance.

The Inlets and Outlets will be tapped as ordered.

NASON'S "STANDARD" PATTERN.

VERTICAL WROUGHT IRON WELDED TUBE RADIATORS.

COLUMN RADIATORS.

Made in halves to encircle columns. Made in five sizes. Usual height, 3 feet.

Pattern Number.	No. of Tubes.	Sq. Feet of Radiating Surface.	Outside Diameters at Floor.	Centres of Holes above Floor.		Inlets.	Outlets.	Diameter of Opening in the Base — Inches.	Price for Plain.	Price for Bronzed.

5	160	160	38¼	4⅝	4	1¼	1¼	16	85.00	96.00

NASON'S "DUPLEX" PATTERN.

VERTICAL WROUGHT IRON WELDED TUBE RADIATOR.

Size Tubes 8 x 24, 192 Tubes, equal to 192 Square Feet of Surface.

Outside Dimensions, Length 4 ft. 5½ in., Width, 24½ in.

To our large assortment of RADIATOR PATTERNS we have recently added the size shown above to meet an increasing demand for a Radiator which, while having a larger amount of heating surface, would occupy comparatively little floor area.

There are so many instances in which this is desirable, that the immediate popularity of the radiator is assured. It will be observed from the cut that the rows of tubes are arranged in groups of two, thus leaving a large provision for admitting air up through openings in the base, and rendering the inside rows of tubes nearly as efficient as those on the exterior.

A stock of these, both plain and bronzed, is carried, from which immediate shipments can be made.

Price, plain.....	95.00
“ bronzed.....	110.00
Marble Top, extra, net.....	15.00

We have also patterns for Radiators of special patterns as follows :

7 Tubes wide and 12 tubes long, the tubes arranged “Staggered,” containing in all 81 tubes.	
Price.....	40.00
6 Tubes wide and 12 tubes long, with Open Base, containing in all 72 tubes.	
Price.....	35.00

32	80	192	160	144	120	96	72	72	64

Unless otherwise ordered, the Rococo Radiators are tapped 2 inches, and bushed according to list on page 380.

Each section is 10 inches wide. Width of legs, 10¼ inches.

All openings will have right-hand threads, unless otherwise ordered.

Top of each hot water leg section has 1½ inch plug, which can be taken out to make top connection when desired.

Can furnish Rococo Radiators connected either with right and left hand threaded nipples or with slip nipples, as customer may prefer.

Distance from floor to center of either supply or return tapping is 4½ inches, single pipe steam; 4½ inches supply, 4 inches return, for double pipe steam; hot water, 4½ inches either supply or return.

* In estimating length of Radiator, allow ¾ inch for each bushing.

32	80	160	160	128	106¾	85½	74½	64	64

Unless otherwise ordered, Ideal Steam Radiators in 38-inch Height are tapped 2 inches and bushed according to list on page 380; other heights are tapped *ad hoc* according to same list.

Each section is 7½ inches wide. Width of legs, 8½ inches.

All openings will have right-hand threads, unless otherwise ordered.

Connected at bottom with 2-inch right-hand threaded nipples.

Distance from floor to center of tapping: single pipe Steam, 4 inches; double pipe Steam, supply 4½ inches, return 4 inches. In other than 38-inch Height of Ideal Steam Radiators, distance from floor to center of either supply or return tapping is 4½ inches.

* In estimating length of 38-inch Ideal Steam Radiators, allow ½ inch for each bushing.

Unless otherwise ordered, the Italian Flue Radiators are tapped 2 inches, and bushed according to list on page 380.

Each section is 8½ inches wide.

All openings will have right-hand threads, unless otherwise ordered.

Connected with extra heavy right and left hand threaded nipples; Steam, 2 inches at bottom; Hot water, 1½ inches at top, 2 inches at bottom.

Top of each Italian Flue Hot Water leg section has 1½ inch plug, which can be taken out to make top connection when desired.

Distance from floor to center of supply tapping: single pipe Steam, 4 inches; double pipe Steam, 4½ inches supply, 4 inches return; Hot Water, 4½ inches supply and return.

*In estimating *length* of Radiator, allow ½ *inch* for each bushing.

32	80	160	128	$106\frac{2}{3}$	$85\frac{1}{3}$	$74\frac{2}{3}$	64

Unless otherwise ordered, the above Radiators will be tapped 2 inches and bushed in accordance with list on page 380.

*Perfection Hot Water is not made in 23-in. height.

Each section is $7\frac{1}{4}$ inches wide. Width of legs, $9\frac{1}{4}$ inches.

All openings will have right-hand threads, unless otherwise ordered.

Perfection Steam connected at bottom with extra heavy 2-inch, right and left hand threaded nipples; Hot Water, $1\frac{1}{2}$ inches at top and bottom.

Distance from floor to center of tapping: single pipe Steam, 4 inches, double pipe Steam $4\frac{1}{2}$ inches supply, 4 inches return; Hot Water supply and return, $4\frac{1}{2}$ inches.

* In estimating length of Radiator, allow $\frac{1}{2}$ inch for each bushing.

Top of each Perfection Hot Water leg section has $1\frac{1}{2}$ -inch plug, which can be taken out to make top connection when desired.

Unless otherwise ordered, National Single Column Steam Radiators are tapped *solid*, according to list on page 380. Unless otherwise ordered, National Single Column Hot Water Radiators are tapped 2 inches, and bushed according to list on page 380.

Each section is 4½ inches wide. Width of legs, 5½ inches.

All openings will have right-hand threads, unless otherwise ordered. National Single Column Radiators for Steam are connected with 2-inch, right-hand threaded, extra-heavy nipples; for Hot Water, 2½-inch extra-heavy slip nipples, at top and bottom.

Distance from floor to center of tapping is 4½ inches, for both Steam and Hot Water.

* In estimating *length* of this Radiator for Hot Water, allow ½ inch for each bushing.

AMERICAN PRACTICE OF WARMING BUILDINGS BY STEAM.

"The application of steam to the warming of buildings in the United States originated with the late Mr. Joseph Nason. He was not only the first to make the attempt, but also the originator, improver and adapter of much that is essential and now implicitly followed in the general arrangement and details of the apparatus employed. His earliest endeavor in America was to adapt the Perkins system of hot water inside small tubes for meeting the severity of that climate. The large extent of warming surface and the great strength presented by steam apparatus constructed of small and comparatively inexpensive wrought-iron tubes, and the facility thereby afforded for transmitting heat in any direction from a central source, are merits which led to so rapid a development of this system of warming, that by 1860, or in less than 20 years, there were already many hundred establishments throughout America for the manufacture of the apparatus.

With the maturing of this system was associated the name of Mr. James J. Walworth, of Boston, brother-in-law and partner of Mr. Nason."—*From a paper by* ROBERT BRIGGS, *M. Inst. C.E.*

The method of warming buildings by steam depends upon the rapid condensation of steam into water when admitted into any vessel which is not so hot as itself. At the moment of condensation the latent heat of the steam is given out to the vessel containing it, and thus diffuses the heat to the surrounding space.

A low-pressure gravity apparatus is the most healthful, economical, cleanly and perfect heating appliance known, and may be constructed to heat a single room or the largest building with a uniformity which cannot be attained by any other means.

A gravity apparatus is one without an outlet whose circulation is perfect, wasting no water and requiring no mechanical means for returning the water of condensation to the boiler. It has been very properly likened unto the circulation of blood in the human system.

This form of apparatus is extensively employed in warming private houses, churches, schools and other public buildings, with very satisfactory results. Its chief merits are, its safety, noiselessness, the ease with which it is managed, the low and uniform temperature of its surfaces, and the positive return of the water of condensation to the boiler under all conditions.

A Low-Pressure Gravity Circulation Apparatus consists of—

The Boiler with its various attachments for the automatic regulation of its draughts and pressures.

Main Steam Pipes and Risers for conveying the steam to the various parts of a building to be warmed, and the corresponding return risers and mains for the return of condensation to the boiler.

Relief Pipes for relieving the mains and risers of the water of condensation and for equalizing the pressure throughout the apparatus.

Radiators or other heating surfaces for the several rooms to be warmed, with their necessary valves and connections.

There are three systems by which the steam may be communicated when desired.

1st. *By direct radiation*, consisting of Radiators as illustrated on pages 356 to 359, or other surfaces placed within a room or building to warm the air and maintain its temperature. This system is not connected with any definite method of ventilation.

2d. *By direct-indirect radiation*, embracing radiating surfaces placed within or partly within the several rooms to be warmed, in direct communication with some system of ventilation. The

heaters are usually placed on outside walls or under windows, to which air is admitted through flues from outside the building. They warm the air again and again, and also all that is admitted for ventilation. This form of heater is illustrated on pages 360 to 364.

3d. *By indirect radiation*, embracing all heating surfaces placed outside the rooms to be warmed, and can only be used in connection with some system of ventilation. This form of surface warms only the air that passes into a room, and has to raise the temperature of all the air admitted to that necessary to maintain any desired temperature, and make up the loss by ventilation. This surface is generally divided into many parts and placed near the lower ends of vertical flues leading to the several rooms to be warmed. For this method of surface a building should be arranged especially with some definite system of flues sufficient to change the entire air of an apartment at least once in an hour.

There are five systems by which a building may be furnished with circulation pipes for a steam apparatus.

1st. *With main steam pipes and risers*, with accompanying return pipes. When properly constructed and with pipes of sufficient area, this method will work satisfactorily at any pressure, and is the system usually employed in large buildings.

2d. *With main steam pipes and risers*, with accompanying return main and with separate return risers for each coil or heater. These several return risers must not connect with each other except below the water line of the boiler. When properly constructed this method will be perfectly noiseless and the air in the pipes is readily disposed of. This system should always be used in private houses and in buildings where extremely low pressures are employed.

3d. *Main steam pipes and risers* with corresponding return mains, but without separate return risers, the steam risers conveying the water of condensation back through a relief to the main return pipes on floor of basement.

4th. *A single pipe system* in which there is but one steam pipe run from the top of the boiler and thence vertically to the several radiators which it is to supply—single branches being taken off for each. The water of condensation returns through these to the steam pipe, and considerable pitch is necessary to insure the water returning against the steam current.

This system is not advised except where the distances to be run horizontally are small and the radiating surfaces standing nearly in a line above the other.

5th. *A single pipe for every heater* runs direct from the top of the boiler, rising continually toward the heaters, and with sufficient area to allow the steam to rise to the heaters, while the water of condensation is returned through the same pipes to the boiler. This system is identical with that described in No. 4, except that the steam supply pipe being sub-divided there is less difficulty likely to occur from conflict of the currents of steam and water of condensation.

By systems Nos. 3, 4 and 5 a slight saving in the first cost of the apparatus is made, consisting of a return line of piping, and rendering necessary but a single valve for each of the heaters: These systems are not, however, recommended except for very small apparatus.

The low pressure gravity apparatus depends for a circulation on the difference of level of water in the return riser and the boiler without regard to the steam pressure in any part of the distributing pipes, but the maximum pressure of steam carried must never exceed the equivalent of a difference in the level of the water between the water line of the boiler and the lowest point of the distributing main.

To return the water of condensation in the apparatus directly to the boiler under all conditions of pressure, the main pipes must be large enough to maintain the pressure of the boiler to within one pound in every part of the apparatus, and the water line of the boiler should be not less than four feet from the bottom of the horizontal main at its lowest part, though somewhat less difference in level can be used with safety, provided a less difference of pressure is carried between the flow and return mains.

STEAM BOILERS.—Boilers for steam warming should have few parts and be as simple in their construction as it is possible to make them. They should admit of easy access for cleaning and repairs, and be capable of evaporating as much water as the pipes can condense in equal times. The most economical size is a medium one, and a departure therefrom occasions a loss of effect, a very large or small boiler giving less duty for fuel consumed than a medium size

properly proportioned to the work to be done. Boilers are recommended that have the largest amount of direct fire surface with a minimum of indirect surface, as it is desirable in house heating to have slow combustion in order to reduce as much as possible the necessary attendance.

The form of boiler as illustrated on page 344 is specially commended as possessing the important features necessary for the economical generation of steam. It will be noticed that every part of its surface is in direct contact with the gases of combustion, while its proportion of heating surface to grate is larger than in any other form in general use, being 38 feet to 1 of grate, or 25 per cent. greater than in any other form now in the market.

To Estimate Size of Boiler.—For boilers of moderate heating surface, such as have been in general use for house warming, the ordinary method of estimating the size of boiler to be used has been, first, to obtain the amount of steam likely to be condensed by the radiating surface, and from this adapt the boiler accordingly.

Economy is, however, chiefly obtained by so proportioning the boiler that for every square foot of grate area there should be the largest practicable amount of heating surface over which the flame and smoke are to be passed and cooled on their way to the flue. It is obvious that the more nearly the gases are cooled to the actual temperature of the boiler before being ejected, the less heat is lost and the greatest number of heat units retained for each pound of coal burned.

It has been found by actual experiment that vertical tube radiators emit about $2\frac{1}{2}$ heat units per square foot per hour for each degree difference between the temperatures of the pipe surface and the surrounding air; so that with pipe surface at 212 degrees and the air at 70, their difference in temperature would be 142 degrees. This, then, multiplied by the above $2\frac{1}{2}$ units, gives an emission of 318 heat units per hour per square foot of surface.

There are approximately 1,000 heat units in a pound of steam, and hence each square foot of surface would condense about .31 lbs. of steam per hour.

In practice like the above, where the boiler surface is deficient and the products of combustion pass to the chimney at a higher temperature than they should, one square foot of boiler surface will evaporate approximately $2\frac{1}{2}$ lbs. of water per hour, and $2\frac{1}{2}$ lbs. divided by .31 gives a ratio of 1 square foot of boiler to about 8 square feet of radiating surface in the apparatus.

Grate Surface.—In house boilers, as usually constructed, where the above evaporation of $2\frac{1}{2}$ lbs. of water to the square foot of boiler surface per hour is obtained, the ratio of surface to grate is about as 20 or 25 to 1; and estimating a coal consumption of say 8 lbs. per hour, with an approximate effect of 8 lbs. of water to each pound of coal, their evaporation per square foot of surface will be: $8 \times 8 = 64 \div 25 = 2.6$ lbs. of water per square foot per hour.

In the "*Equator*" Boiler, as illustrated on page 344, an abrupt change from the old proportion of surface to grate has been made—the object being to obtain from the products of combustion as large an amount of heat produced by coal consumption as possible. For the purpose of comparison we will assume that the amount of coal to be consumed per square foot of grate per hour in this boiler is the same as in the above instance cited, viz., 8 lbs.

By the Equator boiler having the large proportion of surface to grate of about 38 to 1, it is obvious that while the temperature of the escaping gas into the flue will be lower, the actual number of units of heat absorbed by the whole average surface will be less per square foot.

The whole number of feet, however, being greater, the net saving is higher.

The result of this extension of boiler surface is to raise the evaporation from each pound of coal burned from 8 lbs. of water to 10—estimated at 212 degrees water to 212 steam.

Comparing this with the previous statement as to evaporation per square foot of surface per hour, we have $8 \times 8 = 64 \div 25 = 2.6$. The same reasoning with the Equator gives us: $8 \times 10 = 80 \div 38$ is equal to 2.1 lbs. of water only per square foot of surface per hour.

By comparing these we have in the case of the ordinary boiler 2.6×25 as against 2.1×38 , giving 650 effective units retained by the ordinary boiler, as against 798 in the Equator, or *twenty-two per cent. saving*.

The consumption of fuel per square foot of grate, under conditions as usually found in private houses, with apparatus arranged to work automatically and run with an accumulation of ashes.

will be from five to eight pounds per hour, while with larger boilers fired regularly and with ordinary good draught, ten pounds will form a fair average.

The chimney must be capable of passing sufficient air for the largest consumption of fuel likely to be used, less air will not answer, while more will do no harm. Its area should be about 18 square inches for a boiler consuming each 12 lbs. of coal per hour, or about $1\frac{1}{2}$ square inches per pound of coal consumed. An 8x12 chimney is the smallest that should be built in a house for a heating apparatus.

Safety Valves.—These should always be of sufficient area to allow the greatest quantity of steam ever likely to be formed to escape freely.

A formula for finding the size of safety valves is to divide the pounds of water evaporated per hour by 150 for required area of valve in square inches.

Damper Regulators, water feeders, gauge cocks, and other boiler attachments are so familiar and their uses so well understood and appreciated that further comment is not necessary here.

MAIN STEAM PIPES, RISERS, Etc.—Nearly all the success of an apparatus depends on its steam mains, their sizes and how they are run. They should always be of liberal dimensions, depending on the pressure of steam used and the extent of the surfaces employed. A low pressure gravity apparatus requires the largest pipes, though it may be stated that what will answer for such work will answer equally well for any other form of apparatus. The main steam pipe should be taken at once from top of boiler as high as may be convenient, so that its level may be as far above the water line of the boiler as possible. The main valve should be placed in its highest part, so that condensation may not find lodgement on either of its sides.

The pitch of a main steam pipe should drop slowly as it recedes from the boiler, say $\frac{1}{2}$ inch in 10 feet, so that the steam and water may flow in the same direction. The return main should be pitched toward the boiler at about the same inclination.

All main steam pipes and steam risers should be connected at their lowest levels by relief pipes run to or connected with the main return pipes, or to the return risers below the water line in the boiler, to take from them any condensation that may be formed. These relief pipes also serve to equalize the pressure throughout the apparatus, or the return lines may be all run below the water line of the boiler, in which case the connecting lines spoken of are unnecessary.

From the main supply pipe, risers are taken and run to the several parts of the building to be warmed, provision being made between the floors, in placing outlets, for their due expansion. The mains should not be taken too near walls up which risers run, as scarcely anything can withstand the expansion of iron, which in 100 feet and heated to a temperature due to 100 pounds pressure amounts to 2.3 inches.

The Steam Risers should be large for low pressure steam. The general practice is to reduce one size for each floor, though they should never be less than $\frac{3}{4}$ in.

Return Risers convey the condensation from the radiating surfaces in the various apartments to the return main pipe which communicates through a check valve (which may or may not be used) back to the boiler.

Return Pipes are usually run one size less than the feed pipes, and never less than $\frac{3}{4}$ inch, nor less than $\frac{1}{2}$ the diameter of the feed pipes. A thorough drainage of steam pipes may always be depended upon as a means of preventing cracking or pounding noises.

When *automatic air valves* are employed, a $\frac{3}{8}$ -inch pipe should be arranged, with outlets to each floor, for connection to the radiating surfaces, and should extend to and connect with the sewer pipe outside of all traps.

There is no fixed rule for determining the sizes of pipes. In general practice, the area of the cross section of a 1 inch pipe—.7854 square inches—is taken as a unit in the rating of steam pipes,

and the area of a 1 inch pipe in the main at the boiler to each 100 square feet of heating surface, mains included, has been accepted by steam fitters as the result of best experience.

SIZES OF MAIN STEAM AND RETURN PIPES.

Radiating surface in square feet to be supplied.	Size of steam pipes.	Size of return pipes.
125.....	1¼	1
125 to 200.....	1½	1¼
200 to 500.....	2	1½
500 to 1000.....	2½	2
1000 to 1500.....	3	2½
1500 to 2500.....	3½	3

When mains and surfaces are very much above the boiler, the pipes need not be as large as given above, under very favorable circumstances and conditions a 4 inch pipe may supply from 2,000 to 2,500 feet of surface, a 6 inch pipe for 5,000 feet, and a 10 inch pipe for 15,000 to 20,000 feet if the distance of run from boiler is not too great. Less than 1½ inch pipe should not be used horizontally in a main unless for a single radiator connection. The return sizes named are large enough in ordinary pipe work, though when horizontal pipes with many fittings are used they should be of the same diameter as the steam pipes.

Generally when condensation is returned to the boiler by gravity, the diameter of mains should be equal in inches to one-tenth of the square root of the radiating surfaces used in square feet; thus a 1 inch pipe will supply 100 square feet of surface, or with 900 square feet of surface the supply pipe should be. $\sqrt{900} = 30 \div 10 = 3$ " diameter.

The areas of pipes increase rapidly with each increase of their diameters, circular pipes being to each other as the square of their diameters. When a pipe has its diameter doubled, its surface is likewise doubled, while its area is increased four-fold. The increase of the area of pipes for each inch of increase of their diameters is an arithmetical progression whose common difference is 2, the first term being 1.

A small pipe has very much greater surface, compared to the volume of steam or water contained, than a large one. Experiments have shown that the units of heat given off by a square foot of surface are for large diameter horizontal pipes (say 2½" to 4"), 1¼, while in vertical tube radiators 2¼ units are emitted per hour per degree difference between the temperature of the pipe and the ambient air.

Expansion and Contraction.—Scarcely anything can withstand the expansion of iron. It expands from 32° to 212°, about $\frac{1}{800}$ of its length, which in 100 feet equals 1½ inches. The expanding power of a 2" pipe when heated to a temperature of 100 pounds steam, or to 338°, exerts a force sufficient to move 25 tons.

Cast iron expands $\frac{1}{180000}$ of its length for each degree Fahr. it is subjected to within ordinary limits while in its solid state.

Wrought iron expands $\frac{1}{154000}$ of its length for each degree Fahr. To find the expansion of a line of pipe, multiply its length in inches by the number of degrees of temperature applied and divide the product by 154,000 for required expansion in inches; thus $100' \times 12" = 1200 \times 338^\circ = 405600 \div 154000 = 2.7$ inches.

Special attention, then, must be given to the expansion and contraction of pipes and allowance made for it. Pipes and branches must be unconfined, especially in the direction of their length.

Expansion Joints should not be used if the expansion can be compensated for in any other way. In private houses they can be avoided by making right angle turns, etc.

RADIATORS are made in a variety of forms and generally of wrought and cast iron. Their measure of efficiency, as transmitters of heat, is the weight of steam they will condense to water in equal times. From experiments and tests that have been made by experts of unquestioned character it has been proven beyond all question that radiators constructed of wrought iron tubes—possibly because of their thinness of metal as compared with that of cast iron surface—is very considerably the more efficient.

The *Nason form of Vertical Tube Radiator* was invented by Mr. Joseph Nason about 1860, and has been in constant service since that time, giving positive satisfaction under every condition possible to warming apparatus. They are still the leading and most efficient form of surface to be had. They are made in a large number of sizes and forms, as is shown on pages 353 to 370.

Radiators should be proportioned to the cooling surfaces in a building and to the quantity of fresh air admitted into an apartment for the purpose of ventilation. Heat has the remarkable property of passing through moderate thicknesses of air and gases without appreciable loss, so that air is not warmed by radiant heat but by contact with surfaces that have absorbed the radiation.

Table showing the powers of different substances for transmitting heat:

Window Glass.....	1000
Oak or Walnut.....	66
White Pine.....	80
Pitch Pine.....	100
Lath or Plaster... ..	75 to 100
Bricks, rough.....	200 to 250
Bricks, whitewashed.....	200
Granite or Slate.....	250
Sheet Iron.....	1030 to 1110

A square foot of glass will cool 1.279 cubic feet of air from the temperature inside to that outside per minute, and outside wall surface is generally estimated at one-fifth of the rate of glass in cooling effect.

It is very difficult to lay down a fixed rule for apportioning radiating surface to cubical contents of space, there are so many conditions of position and exposure which must be taken into consideration in determining relative proportions; and again, it is evident that the amount of surface necessary for a well constructed building would not be sufficient for a poorly constructed one.

The cubical contents of a room have but little to do with the surface required, still it may be considered a convenient factor for rough calculations, and the ordinary rule of thumb method, often used, is to take the product of the length, breadth and height to equal space contained; mark off the two last figures and call it square feet of surface required, adding for exposed or corner rooms 15 to 30 per cent. For low pressures—2 to 5 lbs.—as much as 100 per cent. is sometimes added, according to size and position of rooms and the purposes for which they are intended.

The following *formula for estimating surfaces* is recommended :

Add together the square feet of glass, plus the cubic feet of air required to be changed per minute, and one-twentieth of surface of outer walls. Multiply this sum by the difference between the temperature inside and outside of building, and divide the product by the difference between the temperature of the pipe surface and the required temperature of the air inside, for the surface required in square feet.

One square foot of surface will heat from 40 to 100 cubic feet of space to 75° in — 10° latitudes. This range is intended to meet conditions of exposed or corner rooms of buildings, and those less so as intermediate ones of a block. As a general rule, one square foot of surface will heat 70 cubic feet of air in outer or front rooms and 100 cubic feet in inner rooms. In large stores in cities with buildings on each side, 1 to 100 is ample.

Table of approximate proportions of radiating surfaces to cubic capacities to be heated.

One square foot radiating surface will heat	In dwellings, school rooms, offices, etc.	In halls, stores, lofts, factories, etc.	In churches, large auditoriums, etc.
By direct radiation.....	60 to 80'	75 to 100'	150 to 200'
By indirect radiation	40 to 50'	50 to 70'	100 to 140'

Isolated buildings exposed to prevailing north or west winds should have a generous addition made to the heating surface on their exposed sides.

The best positions for radiators are where most cooling is done,—before or under the windows or on the outside walls. Where there are many windows the surface should be divided into a number of radiators.

Radiator Connections are usually of the following size:

For 30 feet of surface,	Inlets should be	$\frac{3}{4}$ "	and Outlets	$\frac{3}{4}$ "
" 60	"	"	"	$\frac{3}{4}$ "
" 100	"	"	"	"
" 150	"	"	"	"

When separate feed and return pipes are used on radiators, steam and return valves are necessary. These valves should never be half opened, and if possible they should be operated together. When operated separately, the return valve should be the first closed and the steam valve the first opened.

Air Valves are usually placed high up on one of the pipes nearest the return end of a radiator.

VENTILATION.—In the warming and ventilation of buildings, the entire process, whatever expedients may be adopted, is dependent upon the expansion and contraction of air; or, in other words, upon the fact that air which has been heated or expanded ascends, and air which has been deprived of heat or contracted descends.

Ventilation is the art of causing air to pass through any place for expelling impure air, or dissipating noxious gases or vapors, so that no portion of air shall be breathed twice in the same place. From every heated surface a current of heated air is constantly rising; and so all surfaces for warming should be placed as near as possible to the floor, since radiated heat has very little effect upon the air below the level of the surface from which it is projected.

An average person requires about one cubic foot of oxygen per minute, or say five cubic feet of common air for respiration.

Warmed fresh air flues should be in or near the outside walls, and foul air flues should be in the inner walls near the floor and ceiling, with register valves so as to use either or both, as necessary.

The velocity of air in heated flues with only natural draught rarely reaches 8 feet per second under any conditions, and 2, 4 and 5 feet respectively are fair averages of velocity for first, second and third floors of a house.

To find time for changing air in a room of known cubical contents through a flue of 1 square foot cross section, multiply the velocity of the air through the flue in feet per second by 60 and divide the product into the cubical space of the room; thus, with velocity of 5' per second equals 300 feet per minute, divided into cubical space of room, say 4,000 cubic feet, equals 13.3 minutes.

A natural current of air is from 2 to 5 feet per second. A 12" flue in a wall will deliver about 10,000 cubic feet of air in an hour on second floor of an ordinary building, and about one-half as much to the first floor, so that flues to first floor should be double the area of those intended for second floors.

The same cause which produces draught in chimneys will, if conditions be favorable, set in motion and discharge vitiated air from rooms. Air in chimneys when heated expands according to a law applicable to all gases— $\frac{1}{480}$ of its volume for each degree Fahr. from 32° to 212°; thus, in a chimney 10' high, if the air is heated 20° it would be expanded in volume $\frac{20}{480}$ of 10 feet or .416 feet in height, and as the velocity of any falling body is $\sqrt{2gh}$, so the efflux of air is equal to 8 times the square root of the difference in the height of 2 columns of air of the same weight but of unequal densities, so $8 \sqrt{.416} = 5.16$ feet per second or 310 feet per minute. Thus is ascertained the ascensional force of a chimney draught, or the velocity with which heated air is forced through a flue or chimney.

Ventilation is more difficult in summer than in winter, because the difference of two columns of equal weight is less in height, the difference in their temperatures being less, so that in summer the number or size of inlets and outlets must be increased and the same restricted in winter.

Tredgold advised making the spaces for admission of air abundantly large, and divided much as possible, aggregating to double the areas in ceiling for its exit.

Ventilation has by some been divided into two branches : plenum—forced by mechanical contrivances, and vacuum—the air is drawn out by mechanical means, or through the agency of heat artificially excited, while fresh air finds an entrance through channels adapted to the purpose

A well arranged apparatus should be made to work at any pressure, and with its heating surface properly proportioned it can be made to meet the exigencies of fall, winter and spring weather by simply carrying a pressure suitable to the occasion.

No heating apparatus is perfect unless it heats thoroughly at all pressures, unless the water of condensation runs back and into the boiler at all pressures, unless it is noiseless under all common conditions, and requires only ordinary attention as to fire and water.

Where a steam engine is available and in daily use, the steam warming pipes of an apparatus may be supplied from the engine boiler, its dimensions requiring to be enlarged at the rate of one cubic foot for every 2,000 cubic feet of space to be heated to 70°. One square foot of boiler surface will supply 7 to 10 square feet of radiating surface, and each horse-power of boiler will supply from 240 to 360 lineal feet of 1-inch pipe, or from 80 to 120 square feet of surface.

The rate of combustion under boilers should not exceed .3 pound of coal per hour per square foot of boiler surface, except when quantity of steam is more important than economy of fuel. Allowing 15' boiler surface to a horse power, the fuel necessary per horse power would equal 4.5 pounds. With an evaporation effect of 8 pounds water per pound of coal, the evaporation per horse power would on this basis equal 36 pounds of water ; or divided by 15, each foot of boiler surface would equal 2.4 pounds of water evaporated.

In steam heating by the expansion system, or where steam is used expansively for heating, the steam is allowed to expand or blow through the pipes, and the quantity used in a given time must be sufficient to carry along the water of condensation which forms in the pipes during transmission.

When scattered buildings are heated from one source, or where boilers are of necessity placed on the level of the radiating surfaces, the expansion system must be employed and the condensation must be taken care of by steam traps. When it is desired to return this condensation to the boiler, we recommend the Return Trap, as shown on page 302 ; but when the condensation is allowed to waste, the Nason Trap as on pages 298 and 301 is by far the best form to be had, as it allows the water to cool to the lowest temperature before escaping. It is provided with a valve to hurry the circulation on starting the apparatus. Its action is intermittent, the frequency of discharge depending on the work it has to do.

With high pressure steam allowed to expand through a building and condense through traps, very much smaller piping will answer.

Very great waste of heat results from discharging into an open tank or into the atmosphere. Thus, one pound of steam requires about one thousand heat units, and same is given out in condensation. When water is pumped into a boiler at 40°, 140° additional heat units are required to raise it to the temperature of returned water, and this is saved in a gravity apparatus, resulting in a saving of over 12½ per cent. of fuel.

To estimate pressure in inches of mercury, multiply the apparent pressure by 2.0376 for inches of mercury above the atmosphere ; thus, 10 lbs. \times 2.0376 = 20.376" of mercury. For absolute pressure add 30", equals 50.37'.

To estimate volume of steam. Add 430 to the temperature of the steam, \times 76.5 and \div absolute pressure in inches of mercury ; thus, steam of 10 lbs. pressure has a tempt. equal to $(240 + 430) \times 76.5 \div 50.37 = 1017$ = volume of steam compared to that of water at 39°.

To estimate weight of a cubic foot of steam at different pressures : Divide 1000 (weight in ounces of one cubic foot of water) by the volume for required weight in ounces ; thus, steam at 40 lbs. has volume of 489 ; $1000 \div 489 = 2.05$ oz. = weight of a cubic foot of steam.

To estimate the number of cubic feet of steam a pound of water will produce at different pressures : Divide the weight of a cubic foot of steam in ounces into 16 for the required number ; thus, 1 cubic foot of steam at 20 pounds pressure has a weight of 1.373 and divided into 16 its weight equals 11.65 cubic feet of steam.

Steam to heat water.—To estimate the quantity of steam required to raise the temperature of water any given number of degrees, subtract the lowest temperature of the water from the required temperature and divide the remainder by 1146, minus the required temperature of the water; thus, to find the weight of steam necessary to raise the temperature of water from 75° to 190°: $190 - 75 = 115 \div (1146 - 190 = 957) = .12$, or 12 per cent. of the weight of the water to be raised in steam.

To find the weight of water a given weight of steam will heat, proceed as above after transposing the divisor and dividend; *i. e.*, divide 957 by 115 = 8.32 times the weight of the steam will be raised 115°.

HOT WATER HEATING.

THEORY OF CIRCULATION.—That all falling bodies gravitate with the same velocity and therefore descend through a certain definite space in a given time is an effect of which gravity is the cause; by it the circulation of hot water is attained. This circulation causes all the water in an apparatus to pass successively through the Boiler and then communicates the heat received to the various apartments to be warmed.

In an apparatus for warming when heat is applied to a Boiler the water becomes lighter, and the water in the lower or return pipe of the apparatus being colder and heavier presses with a greater weight than in the Boiler.

By means of this unequal pressure in the lower pipe the water is forced to circulate through the apparatus, and it will continue to do so as long as the water in the returns have a lower temperature than that in the Boiler and flow pipes, and as one is continually receiving heat while the other is as constantly parting with it an equality of temperature never can occur; if it did the circulation would cease. So we find the circulation of water in an apparatus is caused by the unequal pressure in the “up” and “down” pipes, and is not the result of any alteration in the level of the water contained.

A greater permanence of temperature may be obtained by hot water than by any other method, and it is also superior in its economy of fuel.

The relative weight of steam and water at 212°, are about as 1 is to 1,640. So that a pipe filled with water at 212° contains 1,640 times the matter that it does when filled with steam. When the temperature of the steam falls below 212° condensation begins and continues until all its latent heat is abstracted, it then contains a heating power of an equal bulk of water or as quantity occupying $\frac{1}{1640}$ part of space the steam did. The specific heat of steam as compared to that of water is for equal weights as .305 is to 1. Taking the latent heat of steam at 966° the relative heat from equal weights of condensed steam and water by reducing their temperatures from 212° to 60° is as 7.355 is to 1, but for equal bulks it will be as 1 for steam to 280 for water; therefore, steam will lose as much heat in 1 minute as the same bulk of water will lose in $4\frac{2}{3}$ hours.

The colder the water in the descending pipes as compared with that in the boiler, the more rapid will be the circulation through the pipes.

The gravitating force of an apparatus is inversely proportioned to the temperature that is, it is less as the temperature is greater.

Provision must be made for the escape of air in the pipes, else no circulation can be had. Water while boiling evolves air, and when cooling it imbibes it again; and as air is lighter than water, it lodges in the high parts of the circulating pipes, and allowance must be made for its escape or for carrying it off.

With closed boilers, pipes may be carried to any height, depending only on the strength of the material employed. The higher the ascending and descending pipes are run, the more rapid will be the motion of the water, because of the greater difference in their weights.

The pressure by water is calculated by its columnar height reckoned from the bottom of the vessel, and this pressure on each square inch of surface increases at the rate of about .43 pounds for every foot of perpendicular height.

Neither the principal nor practical working of an apparatus is in the least affected by having any additional pipes leading into or out of the boiler. The effect is the same with more flows than returns, and conversely.

Increasing the number of vertical branches does not increase the pressure in an apparatus if the vertical height is not increased.

Law of Velocity of Flow.—The motive power of the circulation in a hot water apparatus is the difference between the specific gravities of the ascending and the descending pipes. This effective pressure is very small, and is equal to about .73 grains for each foot in height for each degree difference between the pipes; thus, with a height of 12" in "up" pipe and a difference between the temperatures of the up and down pipes of 8°, the difference in their specific gravities is equal to 5.84 grains on each square inch of the section of return pipe, and the velocity of the circulation is proportioned to these differences in temperature and height.

To Calculate Velocity of Flow.—Thus, with a height of ascending pipe equal to 10' and a difference in temperatures of the flow and return pipes of 8°, the difference in their specific gravities will equal 58.4 grains, or $\div 7000 = .008343$ lbs., or $\times 2.31$ (feet of water in one pound) = .0193 feet, and by the law of falling bodies the velocity will be equal to $8\sqrt{.0193} = 1.116$ feet per second, or $\times 60 = 66.9$ feet per minute. In this calculation the effect of friction is entirely omitted. Considerable deduction must be made on this account. Even in apparatus where length of pipe is not great, and with pipes of larger areas and with few bends or angles, a large deduction for friction must be made from the theoretical velocity, while in large and complex apparatus with small head, the velocity is so much reduced by friction that sometimes as much as from 50 to 90 per cent. must be deducted to obtain the true rate of circulation.

Velocity Modified by Areas of Pipe.—The motive power of the circulation increases with the size of pipe; that in 4" being more than 4 times that in 2", which is the relation of their areas, but as areas increase faster than circumferences the larger the pipes the less their relative resistance.

Friction of water in pipes varies according to their arrangement and size, being much greater in small than in large pipes, because of greater surface the water contained is in contact with and its increased circulation on account of its more rapid cooling. By increasing velocity the friction is increased nearly as the square of the velocity.

Water loses less of its heat in small than in large pipes, since it travels more rapidly, and the loss of heat by water is directly as the time and the surface conjointly.

To Increase Activity of Circulation.—There are two ways of increasing the effective or motive power, viz., by causing water to cool a greater number of degrees by transit through greater length of pipe or by exposing it to more surface in proportion to water contained in pipes, and second, by increasing the vertical height; this last is principally depended upon when additional power is required to overcome obstructions.

If the circulation be doubled in velocity, the water will pass through the same length in half the time and lose only one-half as much heat, because the rate of cooling is not proportioned to the distance through which water circulates, but to the time of transit.

Increased velocity is indicative of increased power, and in hot water apparatus it is increased velocity which overcomes unusual obstructions.

Care must be taken in arranging pipes so that water in its descent may not be obstructed by differences of level or angles where air may accumulate, for this effectually prevents circulation by dividing the streams.

Friction increases with velocity, but the latter is checked by friction, and so a mean rate is assumed.

Flow Pipes.—All the flow pipes in an apparatus should have an upward pitch toward the heaters and the return pipes a downward one toward the boiler, in either case about 1 inch in 20 feet will answer.

Pressure in pipes does not aid circulation, because the back pressure always equals the pressure ahead.

Since difference in the temperatures of the two columns is essential, the water should rise as much as possible directly it leaves the boiler while it is hottest and lightest, and do most of its falling just before entering the boiler, when coldest and heaviest; and as the motive power at best is small, every advantage should be taken of it. Flow pipes should be covered to retain heat to point where they are to be used. With the return pipe it is equally important, as any loss of heat at this point reduces the temperature of the water entering the boiler.

The advantage of conveying the water through ascending pipes from boilers is two-fold. It allows the freest escape for the air and steam, which prevent circulation, and also facilitates the circulation by increasing the actual and relative weight of the descending column.

Horizontal Pipe.—The distance through which water will circulate in an apparatus is very considerable; the limit has not been ascertained, as the higher it rises above the boiler the greater distance it will circulate. Generally it is best to shorten circulations, and an apparatus will be more efficient if run through two or more short than through one long circulation; for while impediments are overcome by considerable differences in temperatures, the apparatus is most satisfactory when they do not differ widely.

When a boiler is placed considerably below the pipes and other surfaces the circulation is sure to be rapid, and the circulation should be as short as possible to have but little difference in temperature of flow and return pipes; but when boiler is placed nearly on the level of the pipes it is often necessary to have greater differences in the temperatures, so as to secure a good circulation.

Horizontal leading pipes require to be much larger in proportion to their branches than is necessary with vertical leading or main flow pipes, because the friction in an upward pipe is exceedingly small.

Frequently pipes branching from an upright are required to circulate at different levels, as in the warming of several floors, then either one of two methods may be adopted. First, the mains are run to the highest level, and passing round such rooms descend to and circulate through each of the lower floors in turn, finally returning to the boiler; or each floor may have a separate range of pipes branching out of a main upright supply. By the first method the upper floors receive most of the heat, while the lower ones warm slowly. In the second method, if the laterals are taken at right angles from the upright main, the whole of the water is apt to rise to the upper floor, because of the rapidity with which water circulates in an upright pipe. This may be obviated by arranging checks or valves at the points of the lateral branches, or each floor may have a separate supply pipe rising directly from the boiler to each floor.

Surface in Boilers.—The extent of surface which a boiler should expose to the fire should be proportional to the quantity of pipe to be heated, and a small apparatus should have more surface of boiler in proportion to length of pipe than a larger one, as the fire is less intense and burns to less advantage in a small furnace than in a large one.

It is more economical to work with larger surface of boiler at moderate heat than to keep the boiler at its maximum temperature.

Boilers for hot water apparatus should expose the largest surface to the fire in the smallest space.

They should so effectually absorb the heat from the fuel that as little as possible may escape by the chimney.

They should allow the freest circulation of water throughout their entire extent.

They should not easily get out of order, nor rapidly deteriorate by continued use.

The Nason Boiler.—As meeting all the requirements of a first-class Hot Water Boiler, special attention is directed to the "Gulf Stream" Boiler as illustrated and described on page 348. These are efficient, durable, and being provided with large fire surface, they are unusually economical in their consumption of fuel. The heating surface is so disposed that a large proportion of it is exposed directly to the fire, and the heat developed by combustion is thus more thoroughly absorbed than in any other form of boiler now on the market.

The best forms of heating boilers are proportioned about as follows :

1 square foot of grate surface to about 40 square feet of boiler surface.

1 " " boiler " " 5 " " radiating "

1 " " grate " " 200 " " " "

Grates.—In furnaces of considerable dimensions the fuel can be made to burn a much longer period without attention, as so intense a fire is not required as with a steam boiler, and when properly constructed they ought to burn for ten hours without replenishing.

The size of grate should be proportioned to the surface which radiates heat in a building.

Combustion.—The consumption of fuel on any given area of grate must depend on the rapidity of the draught.

In ordinary house-heating boilers, one square foot of grate will burn from 5 to 8 pounds of coal per hour, depending on the work to be done, and may be depended upon to supply requisite heat to about 175 to 200 feet of radiating surface.

Chimneys require an area of about 1.5 square inches per pound of coal consumed per hour, or for boiler burning say 12 pounds of coal per hour, the area of chimney should be not less than 18 square inches.

Efficiency.—One pound of coal should add about 9,000 heat units to water in a boiler used for heating purposes.

The quantity of heat obtainable by the combustion of any substance is fixed and determinate, depending upon the chemical composition of the substance ; this cannot be exceeded, however advantageously applied. It is also true that in no boiler yet made is it possible to render available the whole of the heat of the fuel, and the ratio as above stated is all that can be absorbed in general house-heating boilers.

Of the several formulæ which have been published for establishing the amount of surface necessary to warm a given volume, there is probably no more accurate method of getting at the result than that given by Hood, who works on the basis of the number of cubic feet of air which the radiation from the walls and windows in an apartment will cool per minute, added to the air necessary for ventilation.

The specific heat of water being 1 and that of air .238, and taking water as 800 times heavier than air, at equal volumes 1 cubic foot of water in losing 1 degree of its heat will raise the temperature of $\frac{800}{238} = 336\frac{1}{3}$ cubic feet of air 1 degree.

He has found by experiment that 1 square foot of glass will cool 1.279 cubic feet of air as many degrees per minute as the temperature inside exceeds the external temperature. He further finds that the radiation of external walls in the building gives only about one-twentieth the above loss by radiation.

He also states that water contained in iron pipe, with its temperature 146.8 degrees above that of surrounding air, will lose 1 degree per minute of its temperature, and that 1 square foot of radiating surface, theoretically, will heat, with 146.8 degrees of temperature above that of the surrounding air, about 250 cubic feet of air per minute.

Bearing these facts in mind, his formula for estimating the surface necessary to heat any given room is, to ascertain, first: The number of square feet of window surface. Multiply this by 1.279. Second—Ascertain the amount of cooling wall surface. Multiply this by 1.279, divided by 20. Then the sum of these two figures will give the number of cubic feet of air which have to be heated as many degrees per minute as the temperature inside exceeds that without.

To this should then be added the number of cubic feet of air required for ventilation for each occupant of the room—which should not be less than 5 cubic feet per minute for each individual.

Having thus obtained the number of cubic feet of air to be heated, the method of ascertaining the amount of surface necessary to warm it is as follows:

Multiply 146.8 by the difference between the required temperature of the building and that of the external temperature: dividing this product by the difference between the temperature of the

radiating surface and the required temperature of the building. This result multiplied by the cubic feet of air to be warmed per minute and then divided by 250 will give the required feet of surface necessary to obtain the temperature desired.

As an instance, we will take a room 10 feet cube, having two windows in it, each containing 18 square feet of glass, or 36' together; and two sides of the room are to be exposed to exterior cooling influence: or $200 - 36 = 164$ of cooling wall surface, we now have $36' \times 1.279 = 46$

feet. Again $\frac{164 \times 1.279}{20} = 8$ feet, making $46 + 8 = 54$ cubic feet of air to be heated. To this

we will add 5 cubic feet of air per minute for, say, 2 people = 10 feet, which, added to our 54, gives us 64 cubic feet of air per minute as the whole quantity to be heated.

We will assume that the temperature of the outside air is zero; the desired temperature of the room 70° , and the temperature of the heating surface 200 degrees. From Hood's formula for

heating air we have then: $\frac{146.3^\circ \times 70^\circ}{200^\circ - 70^\circ} \times \frac{64}{250} = 20$ square feet heating surface, or a ratio of 1

square foot of heating surface to 50 cubic feet of volume, which is evidently a fair approximation.

Until the air of a building is heated to its maximum temperature the glass surface will cool proportionately less air, as the cooling power of the glass is in exact proportion to the difference between the internal and external temperatures.

One square foot of plate or pipe surface at 200° will heat from 40 to 100 cubic feet of enclosed space to 70° —when extreme depression of temperature is -10° . This range is to meet conditions of exposed or corner rooms or buildings and of those less so. When air is constantly changed as for ventilation these proportions must be increased.

APPROXIMATE PROPORTIONS OF RADIATING SURFACES TO CUBIC CAPACITIES OF SPACE TO BE HEATED.

One Square Foot of Radiating Surface will heat with	In Dwellings, School Rooms, Offices, Etc.	In Halls, Stores, Lofts, Factories, Etc.	In Churches, Large Auditoriums, Etc.
High Temperature Direct Hot Water Radiation.. }	50 to 70 cubic feet.	65 to 90 cubic feet.	130 to 180 cubic feet.
Low Temperature Direct Hot Water Radiation.. }	30 to 50 " "	35 to 65 " "	70 to 130 " "
High Temperature Indirect Hot Water Radiation.. }	30 to 60 " "	35 to 75 " "	70 to 150 " "
Low Temperature Indirect Hot Water Radiation.. }	20 to 40 " "	25 to 50 " "	50 to 100 " "

The above proportions will give a temperature in the buildings described of 70° Fahr., thermometer being at zero in outside atmosphere.

Small rooms, rooms with large window surfaces, and with exposed walls and cold aspects, and unusually thick walls and fire-proof tile ceilings and floors, will require more radiating surface in proportion to space than is ordinarily needed. Frame buildings require more surface than brick buildings.

There is no advantage gained in using boilers containing a larger quantity of water than is required for the work to be done. The boilers are always full, the lower pipe bringing the supply of cooled water as fast as the ascending pipe carries off the warmed water.

When the water in an apparatus has been raised to the temperature at which it is desired to run it, no more fuel is necessary to maintain it at this point if the boiler, circulating mains and radiators contain a large volume, than if a small quantity.

It is desirable, however, that the cubic feet of water in an apparatus should be small, for the reason that in first heating it more fuel is required to bring it up to the desired point, and in cooling, an excess of heat may have to be used before the temperature falls to where it is wanted.

All radiators should be placed as near the cooling surfaces—the windows and outer walls—as possible, to prevent currents of cool air across the floors. The kind of radiator is not important, provided proper provision is made for the expulsion of all the air and for free circulation of the water. Wrought iron pipe coils are considerably more effective than cast iron radiators, though not so convenient for use in residences. For the latter cast iron radiators are recommended.

Valves and Connections.—Every radiator or coil should be provided with a valve, which may be placed either on the flow or return pipe, for controlling the circulation and regulating the amount of heat given out.

All radiator and other valves in the circulating system should be “Gate” or similar valves, having full openings to permit the free passage of the water.

Air cocks must be placed at the highest point on all radiators or coils to permit of the escape of air when the system is filled, or the admission of air when the system is to be emptied.

SIZES FOR RADIATOR CONNECTIONS.

1" will supply a radiator containing	50 square feet of surface.
1 1/4" “ “ “ “	125 “ “
1 1/2" “ “ “ “	250 “ “
2" “ “ “ “	400 “ “

Sizes of Mains.—All piping should be laid out with reference to the free passage of the water in the pipes, which will be aided largely by the use of “Y’s,” 45°s and long bends, instead of elbows, tees, etc.

Friction in the pipes hinders circulation, and for this reason no smaller pipes than 3/4" should be used.

Main flow pipes from the heater, from which branches may be taken, are to be preferred to the practice of taking off nearly as many pipes from the heater as there are radiators to supply.

It is not necessary that the main flow and return pipes should equal in capacity that of all their branches. The hottest water will seek the highest level, while gravity will cause an even distribution of the heated water if the surface is properly proportioned.

It is good practice to reduce the size of the vertical mains as they ascend, provided they are connected to radiators just below where each reduction is made.

As with steam, so with hot water, the pipes must be unconfined to allow for consequent expansion of the pipes on having their temperatures increased.

An expansion tank is required to keep the apparatus filled with water, which latter expands 1/34 of its bulk on being heated from 40° to 212°, and the cistern must have capacity to hold certainly this increased bulk. It is recommended that the supply cistern be placed on level with or above the highest pipes of the apparatus, in order to receive the air which collects in the mains and radiators, and capable of holding at least 1/10 of the water in the entire apparatus.

There are two distinct forms or modifications of hot water apparatus, depending upon the temperature of the water.

In the first or open tank system the water is never above 212° temperature, and rarely above 200°. This method always gives satisfaction where the surface is sufficiently liberal, but in making it so its cost is considerably greater than that for a steam heating apparatus.

In the second method, sometimes called (erroneously) high pressure hot water heating, or the closed system apparatus.

This form need not be high pressure. For ordinary steam heating a higher pressure than 10 lbs. is rarely used, and with no thought of danger. In a hot water apparatus with closed system and with a safety valve set to discharge at a pressure of 10 lbs. on the expansion tank, there would be no kind of danger to be feared; its temperature would be about the same as with 10 lbs. steam, and the surfaces of boiler and radiators and other proportions would not require to be any larger nor more costly than a steam apparatus, while it would be quite as effective.

"Thermus," in a recent issue of the *Engineering and Building Record*, says: "In a hot water apparatus up to 212° we may say we have no pressure, being only under the pressure of the atmosphere without, thus made equal. The power to burst things commences at the atmospheric pressure and counts therefrom. Therefore, up to 212° the walls of an apparatus are not strained; beyond this, to increase temperature we must increase the pressure, and must have a closed tank for compressed air or steam or a head of water equal to the pressure desired. Up to 300° the pressure is not dangerous, as with properly proportioned tank the pressure cannot exceed 52 lbs.; beyond 300° the pressure advances rapidly."

There are in a winter season seldom more than eight or ten days when the temperature descends to below zero, and at such times an apparatus suitable for ordinary weather can by means of a moderate increase in the temperature of its water and pressure (say up to 10 lbs.) be made to meet the requirements of increased heat that may temporarily be needed. It is indeed strange, in view of the above statements, known to all engineers familiar with house warming, that there should exist such an aversion to this closed tank system. We have erected a large number of such during the past thirty years, and have yet to meet with a first complaint as to its satisfactory service.

Water that has been boiled freezes sooner than water that has not been boiled.

When salt water is used in an apparatus the effect produced on cast or wrought iron pipes and boilers by 10 per cent. of salt in solution would not be of much importance, although in process of time the apparatus would corrode in some degree. After an apparatus is once filled with salt water any waste that occurs should be replaced by fresh water.

The larger the quantity of salt in water the greater is the degree of cold required to freeze it. Water containing 3 per cent. of salt in solution congeals at 28°, with 6 per cent. at 25.5°, and with 11 per cent. it would freeze at 21½°.

Water at medium temperature can hold in solution nearly 36 per cent. of common salt, and at its boiling point nearly 40 per cent.

Water will receive heat from iron 2.6 times as rapidly as iron will receive it from the fire.

AIR.

Atmospheric air is a mechanical mixture—not chemically combined—and when in its purest state consists of oxygen 20.96 nitrogen 79 and carbonic acid gas .04.

One cubic foot at temperature of 32° Fahr. under a pressure of 14.7 lbs. or 30" of mercury, weighs 565.1 grains or .0807 lbs., and 1 lb. is equal to 12.387 cubic feet. Its weight varies about 1 grain for each degree of heat. It is 773 times lighter than water at 32° Fahr.

The mean weight of a column one foot square and of an altitude equal to the height of the atmosphere weighs 2124.7 lbs., or $\div 144 = 14.7$ lbs. per square inch, or $\div 62.5$ it will support a column of water about 34 feet high, or $\div 846$ lbs. (weight of 1 cubic foot of mercury), it will support a column of mercury 30 inches high.

The vital element in air is oxygen gas, which is remarkable for its wonderful energy, and requires nearly 4 times its weight of nitrogen to dilute it sufficiently to meet the requirements of life. The volume of oxygen in equal bulks of air varies with its temperature; thus dry air at 85° contains 10 per cent. less than at 32°, and when saturated with vapor the difference is 12 per cent.; so that if in winter 1500 feet of air are required, in summer 1650 feet will be necessary to supply the same quantity of oxygen. An average man requires about 1 cubic foot of oxygen per minute for respiration, and this quantity is contained in about 5 cubic feet of common air.

The motions of air and all gases are precisely alike to those of fluids.

The temperature of the air at the surface of the earth varies with the geographical position, local circumstances, and with the height above the sea level. The influence of elevation above the sea is very considerable, varying with the climate, season, and general contour of the ground.

When the slope is gradual the cold produced is about 1° for 430 feet; on steep mountain slopes 1° in about 355 feet, and in balloon ascensions 1° in about 330 feet.

The temperature of the surface of the ground follows closely that of the air, but at a certain depth there is a stratum the temperature of which is invariable throughout the year, and is equal to the mean temperature of the air at that place. Below this the heat increases about 1° for every 58 feet of depth; so that if at the surface the temperature is 62° , water would boil at $212^{\circ} - 62^{\circ} \times 58 = 8700$ feet, or $\div 5280$ at 1.647 miles.

The rate of expansion of air and all other elastic fluids for all temperatures and densities is essentially uniform; from 32° to 212° or 180° they expand from 1000 to 1376 = .00209, or $\frac{1}{479}$ part of their bulk or volume for each degree, and from 212° to 680° they increase in volume from 1376 to 2322, or .00202 per degree.

The specific heat of air under $30''$ of mercury with constant pressure is .238, water being 1.00. When heated with constant volume, the pressure is increased and the specific heat is less than when expansion is permitted.

The ratio of specific heat under constant pressure to that under constant volume is as 1.421 is to 1, and the specific heat under constant volume equals $\frac{.238}{1.421}$, or .1674 with Bar. $30''$. All gases are practically the same.

VARIATIONS IN SPECIFIC HEAT OF AIR AT DIFFERENT DENSITIES.

Mercury. column in inches.	Relative density.	Specific heat of equal volume.	Specific heat per lb. constant pressure.	Specific heat per lb. constant volume.	Cubic feet of air in 1 lb. at 62°
120	4	.476	.119	.0837	3.275
60	2	.336	.168	.1184	6.55
30	1	.238	.238	.1674	13.1
15	$\frac{1}{2}$.168	.336	.2367	26.2
7.5	$\frac{1}{4}$.119	.476	.3348	52.4

The specific heat for equal volumes (that at $30''$ being 1) appears to vary directly as the square root of the pressure in relative densities.

When pressure is not constant the volume of any gas varies as the inverse ratio of the pressure, the temperature being constant; thus, 1 cubic foot of air has pressure of air on it to begin with,

and under 45 lbs. its volume equals $1 \times \frac{15}{15+45} = .25$ cubic foot. When temperature and pressure are different the rule for expansion of gases is: $V' = V \times \frac{P}{P'} \times \frac{458.4 + T'}{458.4 + T}$ in which V, P, T,

equals volume, pressure, and temperature in one case, and V' P' T' the same in another case; thus, 10 cubic feet of air at ordinary pressure and temperature of 60° , would, if heated to 200°

under 40 lbs., become $10 \times \frac{15}{55} \times \frac{458.4 + 200}{458.4 + 60} = 3.7$ cubic feet. Air at 32° heated to 212° , or 180°

becomes $1 \times \frac{458.4 + 212}{458.4 + 32} \times \frac{670}{490} = 1.367$ cubic feet, while experiment shows expansion = 1.375.

Efflux of Compressed Air, etc.—Theoretically, when water or other liquid escape from an orifice into air its velocity of efflux is equal to that of a body falling through the space between surface and the orifice, but this result is greatly modified by shape of the orifice and friction.

Velocity into a Vacuum.—The density of air diminishes as it leaves the earth, but assuming it has the same density as at the earth with Bar. $30''$, to equal which a homogeneous column of

air would be $\frac{30'' \times 13.59}{.00122 \times 12} = 27838$ feet, or $30'' \times 13.59 \times 819 = 333906'' \div 12 = 27825'$, and by rule of falling bodies equals $8 \sqrt{27838} = 1344'$ per second. This is theoretical only. In practice it is largely governed by friction through the pipe and orifice and the area of both.

STEAM.

Steam is pure water expanded by heat into an invisible vapor. Perfect steam is in no way moist, but is as dry as are the permanent gases. It has in a complete degree those properties of fluidity, mobility, elasticity and equality of pressure, in every direction that distinguishes gases.

Saturated steam is the normal condition of steam generated in free contact with water, and same density and same pressure always exist in conjunction with same temperature. It therefore is at both its condensing and generating points, *i. e.*, it is condensed if its temperature is reduced and more water is evaporated if its temperature is raised.

The pressure and density of steam, generated in free contact with water, rise with the temperature and reciprocally its temperature rises with the pressure and density, the higher the temperature the more rapidly the pressure advances. There is but one and a corresponding pressure and density for each temperature. The variations in pressure and density of steam generated in free contact with water are exactly proportionate to the variations of temperature. Under this condition steam is termed "saturated" from its containing the largest amount of water possible at any given temperature.

The pressure of steam at a boiling point of 212° is equal to the pressure of the atmosphere, which is 14.7 lbs. upon a square inch.

The expansive force of the vapor of all fluids is the same at their boiling points.

A cubic inch of water evaporated under ordinary atmospheric pressure is converted into 1,640 cubic inches of steam, or nearly 1 cubic foot, and it exerts a mechanical force equal to raising $14.7 \times 144 = 2,120$ lbs. 1 foot high.

One lb. pressure of steam will support a column of mercury = 2.0376 inches high.

The boiling point of water varies with the pressure of the atmosphere or vapor, under which it is effected.

Steam for heating purposes possesses an advantage over hot water in the ease of its application where great inequalities and frequent alterations of level occur, and particularly when the boiler must be placed higher than the place to be heated. For buildings occupied at intervals steam is more effective than hot water in its rapid generation of heat.

The most prominent of the properties of steam are its high expansive force, its condensation by the abstraction of its temperature, its concealed or undeveloped heat, and the inverted ratio of its pressure to the space it occupies.

The expansive force of steam arises from the absence of cohesion between and among the particles of water. If a known volume of steam of a certain pressure be made to occupy but one-half of its volume its elastic power will be doubled.

Steam has an expanding force always equal to the pressure under which it is generated, and its temperature theoretically is always the same as that of the water in contact with it.

The sum of its sensible and latent heat is always the same and is equal to 1146° above the freezing point of water.

Under ordinary atmospheric pressure 26.36 cubic feet weigh one pound, and it has a gravity about equal to one-half that of air at 34° , but if the temperature of air be increased 160° , the gravity of steam will equal two-thirds of the weight of air. This fact is further alluded to on page 355, being illustrated by the circulation of steam in a Nason Radiator Pipe.

HEAT.

Heat is simply a mode of motion, or an influence by which motion is produced among the atoms of substances. This motion is imperceptible, heat being detected only by a sense of feeling.

It is a universal force and is referred to as cause and effect. Heat and cold are conditions and not substances. They are relatively, not absolutely, different, being merely higher or lower degrees of heat.

The three most apparent effects of heat, so far as they relate to the form and dimension of bodies, are expansion, liquefaction, and vaporization. Its effect is most evident in those bodies which are the least influenced by the attraction of cohesion; thus in solids it is comparatively trifling, in liquids it is much greater, while in gases it is very considerable.

The force with which bodies expand and contract under the influence of an increase or diminution of heat is irresistible, and is one of the greatest forces in nature.

The ratio of expansion in solids and liquids increases with the temperature, while in gases it is sensibly uniform at all temperatures.

A unit of heat is the quantity of heat necessary to raise 1 lb. of water 1° F.

Specific heat is the capacity of a body for heat, and is the number of heat units necessary to raise 1 lb. of any substance 1°. The specific heat of all bodies, except gases, increases with their temperature.

Latent heat is the number of heat units absorbed by any body in passing from a solid state to a liquid, or from a liquid to a gaseous condition.

Heat is transmitted or lost—

By radiation—projected in rays and in straight lines.

By convection—rising in fluid masses or through flues.

By conduction—passing from one body to another in contact.

The heat necessary to warm a pound of water 1° will warm about $4\frac{2}{10}$ lbs. of air 1°, or $2\frac{1}{10}$ lbs. of vapor of water, or 9 lbs. of iron, or nearly 2 lbs. of ice, one degree. The heat necessary to convert 1 lb. of water from 178° (which is about the temperature of return water) to steam is about 1000 units, and this will heat 52,000 cubic feet of air 1°, or 5,200 cubic feet 10°, or 52 feet 100°, without making allowance for the increase of its bulk because of expansion, which for a difference of 100° will equal nearly 20 per cent. of its original bulk.

WATER.

Whether as a solid, liquid, or gas, water is one of the most wonderful substances in nature. At all temperatures above 32° F. the motion of heat is sufficient to keep its molecules from rigid union; but at 32° the motion becomes so reduced that the atoms seize upon each other and aggregate to a solid.

It is composed by a chemical union of oxygen and hydrogen in the proportions of :

By weight, oxygen, 88.9 parts. Hydrogen, 11.1 parts.

By volume, “ 1 “ “ 2 “

Liquids transmit pressure equally in all directions, unchanged and without loss of power. This equality of pressure is their most characteristic property.

Water when heated from 40°—which is nearly the temperature when at its maximum density—to 212°, expands .0433 times its volume, or .000252 of its bulk for each degree, making its increase for 180° equal to 1 cubic foot in 21.41 feet. Below 39.1°, its point of maximum density, its ratio of expansion decreases at first slowly, but progresses rapidly to the point of congelation, where it suddenly expands .0855 of its volume; a cubic foot of ice weighing 57.5 lbs., or about 5 lbs. less than when at 40° temperature. At 46° it has about the same volume as at 32.

It is compressible at the rate of about $\frac{1}{21440}$, or about $\frac{1}{110}$ of an inch in 18 $\frac{1}{10}$ feet by each atmosphere or pressure of 15 lbs. per square inch. When the pressure is removed its elasticity restores its original bulk. By compression, Mr. Perkins, of London, required a pressure of 15,000 lbs. to reduce water $\frac{1}{4}$ th part of its volume. Water at 39.1° is taken as the unit of weight upon which the specific gravity of steam is based.

A United States standard gallon at 39.1° Fah., Barometer at 30" mercury, weighs 8.34 pounds, and is equal to 231 cubic inches.

A pound of distilled water at 39.83° , Bar. 30° , is equal to 27.7 cubic inches, and a cubic inch weighs 252.69 grains. A cubic foot contains 7.48 gallons, and at 39.83° weighs 998 ounces or 62.38 lbs. avoirdupois, and is 828 times heavier than atmospheric air. For ease of calculation its weight is taken as 1,000 ounces or 62.5 lbs.

Water at 1,000 ounces is assumed as unity in the comparison of gravity of different substances.

It evaporates at all temperatures, dissolves more substances than any other agent, and has a greater capacity for heat than any other known substance except hydrogen gas.

Twenty volumes of water absorb one volume of air under atmospheric pressure.

A miner's inch is a measure for the flow of water, and is an opening 1" square through a plank 2" thick under a head of 6" of water to the upper edge of the opening. It will discharge $11\frac{5}{8}$ gallons in one minute.

A cylinder $3\frac{1}{2}$ inches in diameter and 6 inches high will hold almost exactly one quart, and one 7 inches in diameter and 6 inches high will hold very nearly one gallon.

The ratio of fresh water to salt water is about as is 36 to 35 by weight.

HYDRAULICS.—The science of Hydraulics depends on a knowledge of the laws of gravitation. In it velocity and pressure are the two chief factors to be determined in every problem. All calculations showing the discharge of water under pressure are based on the head or depth of water above the outlet usually stated in feet. The universal standard of measurement is the pressure gauge showing the number of pounds pressure on each square inch.

A column of water 1 inch square and 2.31 feet high at 60° is equal to 1 pound, or will give a pressure equal to 1 pound. Hence :

Pounds pressure $\times 2.31$ = head.

Depth of water $\div 2.31$ = pressure per square inch.

“ “ $\times .434$ = lbs. pressure.

Pounds pressure $\div .434$ = head or depth of water.

Water under pressure is subject to the same laws as falling bodies. In a vacuum it will fall 16.1 feet in one second, and increases the velocity of its descent 32.2 feet each second while the descent continues, making the fall for 2 seconds equal to 64.4 feet, and so on. The velocity of a falling body per second is equal to $\sqrt{2gh}$, in which g equals force of gravity and h equals height, or 8 $\sqrt{\text{height}}$. Thus, in a cistern 25 feet deep, with a 1 inch hole in the bottom, the velocity of its efflux = $8\sqrt{25}$ feet = 40 feet. This rule applies to all bodies falling freely in space when not impeded by resistance. Having found the velocity, the next step is to find the quantity discharged. This quantity discharged per minute is equal to the velocity in feet per second \times area of orifice in inches $\times 12$ for inches and by 60 seconds in one minute = number of cubic inches discharged per minute, and this \div by 231, number of inches in a gallon, = gallons discharged per minute. Thus with the above cistern and outlet, $8\sqrt{25} \times .7854 \times 12 \times 60 \div 231 = 98$ gallons per minute. This discharge is theoretical, in practice it varies with the form of the outlet. With the orifice in thin plate the discharge will equal from .6 to .7 of the theoretical quantity. A formula for quick and approximate calculation is $\sqrt{\text{head}} \times \text{diameter of orifice} \times 19.5$ = gallons discharged per minute; thus $\sqrt{25} = 5 \times 1" \times 19.5 = 97\frac{1}{2}$ gallons. Formula for finding quantity of water delivered through pipes of any length, diameter and head :

$\sqrt{425 \times \text{diam. in inches} \times \text{pressure in lbs.} \div \text{length}} = \text{velocity}$. Thus find water delivered per minute through 3,000 feet 3" pipe with a head of 6': $\sqrt{425 \times 3 \times 2.6 \text{ lbs.} \div 3000} = 1.05$ feet per second = velocity, and $1.05 \times 7.07 \times 12 \times 60 \div 231 = 23.1$ gallons per minute = quantity discharged.

In all these calculations account must be taken of two kinds of loss : (1) Loss from velocity of entry occasioned by cross currents and shape of edge of orifice, and (2) loss by friction. This last is the principal cause of loss. The friction of water on smooth surfaces is about $\frac{1}{2}$ pound per square foot when water is moving at the rate of 10 feet per second. If this velocity is increased or diminished, the friction increases or diminishes in proportion to the square of the velocity, thus—

$10^2 = 100 : 20^2 = 400 :: \frac{1}{2} : 2$ pounds. Again:

$10^2 = 100 : 5^2 = 25 :: \frac{1}{2} : \frac{1}{8}$ pounds. So that doubling the velocity increases the friction four fold, and when trebled it is increased 9 times.

Doubling the diameters of pipes increases their circumference or pipe surfaces in the same ratio; but doubling their areas increases same four fold. Since pipes are to each other as the squares of their diameters, doubling the size of a pipe decreases frictional loss at same velocity $\frac{1}{2}$ or the loss by friction is inversely as the size; that in 2" is $\frac{1}{2}$ that in 1", and in a 3" it is $\frac{2}{3}$ that in a 2" pipe.

As an illustration: If pipe one inch in diameter be compared side by side with one two inches in diameter, the areas of their cross section being as one is to four, the velocity naturally is as four is to one in order to deliver any given quantity per hour through either of them. But the frictional resistance on either of their interior surfaces increases some what less than in the proportion of the square of velocities through them.

Taking, however, the velocity as above at 4 to 1, the frictional resistance per given surface becomes 4^2 to 1, or the frictional resistance per square foot is 16 times greater in the one-inch pipe than it is in the two-inch; but there is but one-half the surface in the one-inch pipe that there is in the two-inch, so that we have $16 \div 2 = 8$. Or, while discharging a given quantity of water through a one-inch or a two-inch pipe, the frictional resistance is eight times greater in the smaller size than in the larger.

FRICTIONAL LOSS IN POUNDS PRESSURE IN $2\frac{1}{2}$ " HOSE FOR EACH 100 FEET.

Gallons per minute.	Friction loss in rubber.	Loss in leather.
50	1.40	2.90
60	1.60	3.17
80	2.51	4.25
100	3.65	5.55
200	14.15	17.00
300	32.65	36.65
350	44.90	49.55

In the foregoing formulas, as well as in the case of friction in hose, it is assumed that all the conduits are on nearly straight lines. If the direction of flow is altered to any considerable extent by the interpolation of bends or elbows, the friction will be largely increased.

Formulas for finding areas of pipes required to deliver given quantities of water under given heads, in which A = area in square feet, a = area in square inches; T = time in minutes, t = time in seconds: H = head in feet, h = head in inches.

1. When time is in seconds, head in inches and required area is in square inches—area of discharge pipe = number of gallons $\div .0757 t \sqrt{h}$.

2. When area is in square inches, time in seconds and the head in feet, the required area in square inches will be equal to gallons $\div .26215 t \sqrt{H}$.

3. When area is in square inches, time in minutes and head in inches, the required area in square inches will be equal to gallons $\div 4.542 T \sqrt{h}$.

4. When area is in square feet, time in seconds and head in inches, the required area in square feet will be equal to gallons $\div 10.9 t \sqrt{h}$.

5. When area is in square inches, time in minutes and head in feet, the required area in square inches will be equal to gallons $\div 15.729 T \sqrt{H}$.

6. When area is in square feet, time in seconds and head in feet, the required area in square feet will be equal to gallons $\div 38.75 t \sqrt{H}$.

7. When area is in square feet, time in minutes and head in inches, the required area in square feet will be equal to gallons $\div 654 T \sqrt{h}$.

8. When area is in square feet, the time in minutes and head in feet, the required area in square feet will be equal to gallons $\div 22.65 T \sqrt{H}$.

PUMPS.—The power to raise water depends on the height to be overcome, the quantity to be delivered and the friction in the pump and its connecting pipes, from which is deduced the formula—lbs. of water \times height in feet = number of foot pounds, and this divided by 33000 = horse-power necessary; to this must be added a liberal allowance for friction in the pipes and loss by condensation in the steam cylinders.

When a vacuum is formed in a suction pipe, the pressure of the external air forces the water up the pipe, provided the lift is not too great. Theoretically water can be lifted by suction about 34 feet, but in practice not more than from 20 to 25 feet can be realized.

The nearer pumps are placed to the water the more easily can the water be raised.

Suction pipes should be air tight. They should have a capacity not less than half that of the pump cylinders, and when the lift is near its limit it should be even larger. By using large pipes friction is lessened, as is also the labor employed.

Air chambers contain large quantities of air which, being compressible, acts as a cushion and thus decreases the shocks which occur in suddenly stopping and starting a long water column, whether in the suction pipe or force main.

Water at high temperature, or volatile fluids, cannot be raised any considerable height by suction, because vapor forms, prevents the formation of a vacuum and resists the entrance of the water. When pumps are used for this purpose they must be placed very close to the fluid or be supplied from a head. Pumps and inspirators cannot force water heated to a temperature when steam forms in any quantity, and for this reason feed water is never injected into a boiler at over 212°, and generally at not over 200°.

Double-acting pumps keep up a steady stream and thus economize labor, as every stroke, up or down, is effective. In single-acting pumps every alternate stroke only avails.

Submerged pumps are placed entirely under water, which it forces. They are used when water is foul or gritty, as in cellars, sewers or tanneries.

Hydraulic rams are contrivances for raising small quantities of water to considerable heights by using the momentum of larger quantities flowing downwards. They differ from pumps in that they have no pistons, form no vacuum, and are always placed below the supply. The principle of their operation is: the inertia of the fluid in rapid motion suddenly stopped, as the jarring motion in pipes, and often called water-hammer.

It is estimated that, by conveying water to a ram through from 50 to 60 rods, that about $\frac{1}{4}$ of the water can be discharged at an elevation five times the fall applied to the ram, or $\frac{1}{14}$ of the water to 10 times the fall; thus: if ram have 5 feet fall, $\frac{1}{4}$ of the water can be discharged 25 feet high, or $\frac{1}{14}$ th at 50 feet, or with a fall of 10 feet $\frac{1}{14}$ th can be raised 100 feet.

Steam Pumps.—The ordinary speed at which pumps should be run is not more than 100 feet piston travel per minute. The area of the steam piston \times the steam pressure = the total pressure exerted. The area of water piston \times pressure of water per square inch, is = the resistance. A liberal allowance must be made between the power and the resistance to move pistons at the required speed, for water friction and loss in steam cylinders.

To find horse-power necessary to elevate water to a given height. Formula: Total weight of water in pounds \times height in feet \div 33,000 = horse-power required; to this liberal allowance as before stated must be made.

To find the diameter of a pump cylinder to move a given quantity of water per minute (100 feet of piston being the standard of speed), divide the number of gallons by 4, then extract the square root, and the product will be the diameter in inches of the pump cylinder.

To find quantity of water elevated in one minute running at 100 feet of piston speed per minute, square the diameter of the water cylinder in inches and multiply by 4. Example: Capacity of a 5-inch cylinder is desired. The square of the diameter (5 inches) is 25, which, multiplied by 4, gives 100, the number of gallons per minute (approximately).

HORSE-POWER is a term which has been adopted to express the work developed through a mechanical device by any of Nature's forces, and in the case of the steam engine is taken as the power necessary to raise 33,000 lbs. one foot high per minute; or, as it is commonly expressed, thirty-three thousand "foot-pounds."

It is divided into three classes, termed Nominal, Indicated and Actual.

Nominal horse-power has been used to express the capacity of an engine; the elements thereof being confined to the dimensions of the steam cylinders and a conventional pressure of steam and speed of engine.

Indicated; designates the full capacity in cylinder as developed in the operation, without deductions for friction.

Actual, is the power only as developed by its operation, involving elements of mean pressure, through the stroke applied to the piston, its velocity and a just deduction for friction. Its amount is usually arrived at by the application of a Dynamometer.

The actual horse-power added to the engine friction are equal to Indicated horse-power.

BOILERS should be simple in construction and of the best material. They should be capable of evaporating as much steam as may be required, whether for power or heating purposes.

They should have constant and thorough circulation throughout so as to maintain all parts at one temperature.

They should have large water and steam space to prevent foaming and sudden fluctuations in pressure or water level.

They should be readily accessible for cleaning and repairs.

The furnace is for the proper combustion of fuel, but the boiler proper is for the transfer of heat into useful effect by evaporating water into steam.

The efficiency of a boiler or its power is the volume or weight of steam that it will generate at its operating pressure in a unit of time, or per pound of fuel.

The most economical size of boiler is a medium one, and a departure therefrom in either direction is followed by a loss of effect. An unusually long or a very short boiler giving less duty for fuel used than a medium sized one properly proportioned to the work to be done.

The fire surface of boiler per horse power varies with its size, a small one not being so effective in proportion to the area as a large one, the loss by radiation being greater in proportion as the power is less.

The term horse-power as referring to boilers is very indefinite. It is preferable to estimate their capacity by the pounds of water evaporated per hour. Strictly speaking, there is no such thing as horse-power as applied to steam boilers, since it is only a measure applicable to dynamic effect. But as boilers are necessary to drive engines, the same term has been commonly applied to them.

Watt found in his time that the requirement for a horse-power in the best engine then in use was the evaporation of one cubic foot of water per hour in the boiler. Now it is estimated that good engines require water per hour per horse-power equal to the constant $200 \div \sqrt{\text{pressure}}$, and in the best engines the constant $150 \div \sqrt{\text{pressure}}$.

Horse-Power of Boilers.—The following proportions of heating and grate surfaces for each horse-power are generally accepted as approximately correct: In plain cylindrical boilers, 15 square feet of heating surface and 1 square foot of grate surface.

In flue boilers, 15 feet heating surface and $\frac{3}{4}$ -foot of grate surface.

In tubular boilers, 15 to 16 square feet of heating surface and $\frac{1}{2}$ square foot of grate surface.

A little more grate surface will probably give better results.

COMBUSTION consists in the combination of bodies with oxygen, the result being usually the development of heat and light. The combustibles used in the arts are principally composed of carbon and hydrogen. The carbon combining with oxygen derived from the air forms carbonic acid, and the hydrogen similarly combining forms water.

Carbonic acid is composed of one equivalent of carbon and two equivalents of oxygen, or by weight .2727 carbon, and .7273 oxygen.

Water is composed of one equivalent of oxygen and two equivalents of hydrogen; or by weight, .111 hydrogen and .889 oxygen.

TABLE OF THE CHEMICAL COMPOSITION OF COMBUSTIBLES.

TABLE OF THE CALORIFIC POWER OF COMBUSTIBLES.

	Units of Heat per lb.		Units of Heat per lb.
Hydrogen, burning to water.....	62535.	Wood, in ordinary state of dryness..	5040.
Carbon, burning to carbonic acid.....	12906.	Alcohol	12339.
Carbon, burning to carbonic oxide..	4453.	Oil of Turpentine.....	19505.
Wood, perfectly dried.....	6480.	Bees-wax	18900.

One pound of carbon combining with the necessary quantity of oxygen develops 12906 units of heat, and one pound of hydrogen similarly combining, yields 62535 units. The unit of heat is the amount necessary to heat one pound of water 1° Fahr.

When a combustible contains hydrogen and oxygen in the proportion required to form water, they combine during the process of combustion, but give out no useful heat. If hydrogen alone is present, it yields usefully the full amount of heat due to it. When oxygen is present, but in too small a proportion to combine with the whole of the hydrogen, there remains an excess of hydrogen which yields its due proportion of heat.

The heating power of a combustible is the maximum effect it is capable of producing; although when applied to practice there are sources of unavoidable loss which reduce its useful effect considerably.

The effect of water in a combustible with which it is more or less saturated is two-fold. 1st, the calorific power is reduced in the same proportion, and 2d, part of the heat in the residue is consumed uselessly in evaporating the water. Thus wood perfectly dried yields 6480 units, which, for wood in the ordinary state, containing 20% of water, is reduced to $6480 \times 80 = 5184$ units, but the 20% water, say at 60° , will require for its evaporation $(1178 - 62) \times .20 = 223$ units, so that its useful heat is reduced to $5184 - 223 = 4961$ units.

The heating power of wood varies only with its state of dryness, that is to say, all the different kinds of wood in the same state of dryness, measured by weight, yield sensibly the same amount of heat.

When the chemical composition of a combustible is known, its calorific power is readily calculative; thus the average composition of coal is, carbon, .812; hydrogen, .048; oxygen, .054, and waste, .086; the hydrogen is reduced to .041 hydrogen in excess, the balance combining to form water. From this 1 lb. of coal will yield:

$$\begin{aligned} \text{Carbon.....} & .812 \times 12906 = 10480 \text{ heat units.} \\ \text{Hydrogen in excess.....} & .041 \times 62535 = 2564 \text{ " "} \end{aligned}$$

Again, wood properly dry contains .51 carbon, .053 hydrogen, and oxygen, .417. The hydrogen and oxygen being in proper proportions to form water, combine without yielding any useful heat, and so we have $.51 \times 12906 = 6582$ units per lb. of dry wood.

Air required to support combustion.—A knowledge of the quantity of air necessary for different combustibles is important, in order to determine the sizes of flues, etc.

Carbonic acid is composed of .2727 carbon and .7273 oxygen, and atmospheric air is composed of .773 nitrogen, and .222 oxygen. A pound of carbon will require $\frac{.7273}{.2727} = 2.67$ lbs. of oxygen, which is contained in $\frac{2.67}{.222} = 12.03$ lbs. of air, and as a cubic foot of air at 62° Fahr. weighs .0761 lbs., this is equal to $\frac{12.03}{.0761} = 158$ cubic feet of common air at ordinary temperature. This is the minimum amount necessary for the combustion of a pound of carbon.

Water being composed of .111 hydrogen and .889 oxygen, one pound of hydrogen requires $\frac{.889}{.111} = 8$ lbs. of oxygen, which is contained in $\frac{8}{.222} = 36$ lbs. of air, or $\frac{36}{.0761} = 473$ cubic feet of common air at 62°, and this is the minimum amount of air necessary for the combustion of one pound of hydrogen.

From these elements we can calculate the quantity of air required for the combustion of any combustible whose composition is known. Thus, the average composition of coal is .812 carbon and .048 hydrogen, which last is, as before stated, reduced to .041 hydrogen in excess, and we shall require: $(.812 \times 158) + (.041 \times 473) = 147.6$ cubic feet of air at 62° required for the combustion of 1 lb. of coal; but analyses of the air that has passed through the fires of well-arranged steam boilers show that the air retains 10 per cent. of oxygen unconsumed, so that we may admit of a practical rule that the quantity of air used should be double the minimum theoretical quantity.

In most cases the temperature of air in the chimneys of steam boilers is 550° Fahr., and has double the volume it has at 62°, and with the oxygen half consumed the air required in the chimney will be for the combustion of 1 lb. of carbon $158 \times 2 \times 2 = 632$ cubic feet.

STEAM ENGINE is an instrument by means of which heat is converted into mechanical effect. Water in its state of steam is the medium through which this conversion is effected. An engine is operated by the expansive force of steam.

Experiments have demonstrated that not more than 13 per cent. of the heat generated is utilized even by the very best engines, while the great majority of them fall much below.

The horse power of an engine is equal to lifting 33,000 lbs. one foot per minute.

To find the horse power of an engine, multiply together the area of the piston in inches, the average steam pressure in pounds on the piston throughout the stroke, and the travel of the piston in feet, and divide by 33,000 for the required horse power. Thus, find the horse power of an engine with 40" cylinder, 10' stroke and 20 revolutions per minute, $= 40 \times 40 = 1600 \times .7854 = 1256$ square inches area of piston \times say 30 lbs. average effective steam pressure \times 400 feet travel $= 15,072,000$ "foot-pounds" $\div 33,000 = 457$ horse power. With this steam travels full stroke and exerts its greatest power. When steam is cut off, the average steam pressure must be taken.

The mechanical effect of steam in a cylinder is the product of the mean pressure in pounds and the distance through which it has passed in feet.

Back pressure is the force of uncondensed steam in a cylinder, due to friction in the exhaust pipe or valves, faulty setting of the latter, or in a condensing engine to a faulty vacuum. It is opposed to the course of the piston, and varies from 2 to 5 pounds per square inch.

A SIMPLE METHOD OF CALCULATING INTEREST.

If at 6 per cent., multiply the dollars by the number of days, and divide by 6, and cut off one figure on the right, thus:

EXAMPLE: What is the interest on \$46.25 from April 12 to July 15, which is 94 days?

$$\begin{array}{r}
 94 \\
 \times 46 \\
 \hline
 564 \\
 376 \\
 \hline
 6)4324 \\
 \hline
 .72 \text{ Ans. } .72 \text{ cents}
 \end{array}$$

If at 7 per cent., after following above rule, add $\frac{1}{8}$, thus:

$$\begin{array}{r}
 72 \\
 \frac{1}{8} = \frac{12}{8} \text{ Ans. } 84 \text{ cents.} \\
 \hline
 .84
 \end{array}$$

If at 5 per cent., deduct $\frac{1}{8}$, thus:

$$\begin{array}{r}
 72 \\
 \frac{1}{8} = \frac{12}{8} \text{ Ans. } 60 \text{ cents.} \\
 \hline
 .60
 \end{array}$$

DISCOUNT TABLE.

As many of the goods embraced in this book are sold by discounts, or a series of discounts from their list of prices, it will be found convenient to refer to a table and ascertain at once the equivalent and net remainder.

For instance, a discount of 50, 10 and 5% (erroneously supposed by many to equal 65%) is equivalent to 57 $\frac{1}{4}$ %, and the net remainder, 42 $\frac{3}{4}$ %, is the multiplier with which to ascertain the NET price.

Discount. Per Cent.	Equiv- alent.	Net.	Discount. Per Cent.	Equiv- alent.	Net.	Discount. Per Cent.	Equiv- alent.	Net.

TABLE SHOWING THE NUMBER OF DAYS FROM ANY DATE IN ONE MONTH
TO THE SAME DATE IN ANY OTHER MONTH:

FROM	JAN.	FEB.	MAR.	APRIL.	MAY.	JUNE	JULY.	AUG.	SEPT.	OCT.	NOV.	DEC.
January	365	31	59	90	120	151	181	212	243	273	304	334
February	334	305	28	59	89	120	150	181	212	242	273	303
March	306	337	305	31	61	92	122	153	184	214	245	275
April	275	306	334	365	30	61	91	122	153	183	214	244
May	245	276	304	335	305	31	61	92	123	153	184	214
June	214	245	273	304	334	305	30	61	92	122	153	183
July	184	215	243	274	304	335	305	31	62	92	123	153
August	153	184	212	243	273	304	334	305	31	61	92	122
September	122	153	181	212	242	273	303	334	305	30	61	91
October	92	123	151	182	212	243	273	304	335	305	31	61
November	61	92	120	151	181	212	242	273	304	334	305	30
December	31	62	90	121	151	182	212	243	274	304	335	305

NOTE.—If Leap-year, add one day if February be included.

EXAMPLE: How many days from February 12 to August 12? Look for February at left-hand, and August at the top. The angle and answer is 181 days.

If different dates of different months are required, add the odd number of days to the even days, thus: Time, from April 12 to July 15.
EXAMPLE: From April 12 to July 12 is 91 days, and from the 12th to the 15th of July it is 3 days, which, added to the 91 days gives the time from April 12 to July 15, or answer, 94 days.

FOR CALCULATING WAGES FROM ONE HOUR TO SIX DAYS, AT FROM
\$1.00 TO \$20.00 PER WEEK.

For 6 Days.	1 Day.	2 Days.	3 Days.	4 Days.	5 Days.	1 Hour.	2 Hours.	3 Hours.	4 Hours.	5 Hours.	6 Hours.	7 Hours.	8 Hours.	9 Hours.
